How might women's and men's development vary as they go through their adult years? How might gender be linked with aging?

rapport talk The language of conversation; a way to establish connections and negotiate relationships; preferred by women.

report talk Language designed to convey information; a communication style preferred by men.

Gender and Communication

Stereotypes about differences in men's and women's attitudes toward communication and about differences in how they communicate with each other have spawned countless cartoons and jokes. Are the supposed differences real?

When Deborah Tannen (1990) analyzed the talk of women and men, she found that many wives complained about their husbands by saying that "He doesn't listen to me anymore" and "He doesn't talk to me anymore." Lack of communication, although high on women's lists of reasons for divorce, is mentioned much less often by men.

Communication problems between men and women may come in part from differences in their preferred ways of communicating. Tannen distinguishes *rapport talk* from *report talk*. **Rapport talk** is the language of conversation; it is a way of establishing connections and negotiating relationships. **Report talk** is talk that is designed to give information; this category of communication includes public speaking. According to Tannen, women enjoy rapport talk more than report talk, and men's lack of interest in rapport talk bothers many women. In contrast, men prefer to engage in report talk. Men hold center stage through verbal performances such as telling stories and jokes. They learn to use talk as a way to get and keep attention.

What are some gender differences in communication?
Streetangel/Getty Images

How extensive are gender differences in communication? Research has yielded somewhat mixed results, although studies do reveal some gender differences (Anderson, 2006). One study of a sampling of students' e-mails found that people could accurately guess the writer's gender two-thirds of the time (Thompson & Murachver, 2001). Another study revealed that women make 63 percent of phone calls and when talking to another woman stay on the phone longer (7.2 minutes) than men do when talking with other men (4.6 minutes) (Smoreda & Licoppe, 2000). However, meta-analyses suggest that overall gender differences in communication are small in both children and adults (Hyde, 2005, 2014; Leaper & Smith, 2004).

Women's Development

Tannen's analysis of women's preference for rapport talk suggests that women place a high value on relationships and focus on nurturing their connections with others. This view echoes some ideas of Jean Baker Miller (1986), who has been an important voice in stimulating the examination of psychological issues from a woman's perspective. Miller argues that when researchers examine what women have been doing in life, a large part of it is active participation in the development of others. In Miller's view, women often try to interact with others in ways that will foster the other person's development along many dimensions—emotional, intellectual, and social.

Most experts stress that it is important for women not only to maintain their competency in relationships but also to be self-motivated (Brabek & Brabek, 2006). As Harriet Lerner (1989) concludes in her book *The Dance of Intimacy*, it is important for women to bring to their relationships nothing less than a strong, assertive, independent, and authentic self. She emphasizes that competent relationships are those in which the separate "I-ness" of both persons can be appreciated and enhanced while the partners remain emotionally connected with each other.

In sum, Miller, Tannen, and other gender experts such as Carol Gilligan note that women are more relationship-oriented than men are—and that this relationship orientation should be valued more highly in our culture than it currently is. Critics of this view of gender differences in relationships contend that it is too stereotypical (Hyde & Else-Quest, 2013; Matlin, 2012). They argue that there is greater individual variation in the relationship styles of men and women than this view acknowledges.

In the field of the psychology of women, there is increased interest in women of color. To read about the work and views of one individual in this field, see the *Connecting with Careers* profile.

Tom Cruise (*left*) played Jerry Maguire in the movie *Jerry Maguire* with 6-year-old Ray, son of Jerry's love interest. The image of nurturing and nurtured males was woven throughout the movie. Jerry's relationship with Ray was a significant theme in the movie. It is through the caring relationship with Ray that Jerry makes his first genuine movement toward emotional maturity. The boy is guide to the man (Shields, 1998). Many experts on gender stress that men and boys would benefit from engaging in more nurturant behaviors.
Pictorial Press Ltd/Alamy Stock Photo

inconsistent. Not only do men experience stress when they violate men's roles, they also are harmed when they act in accord with men's roles. Here are some of the areas where men's roles can cause considerable strain (Levant, 2001):

- *Health*. Men die 8 to 10 years earlier than women do. They have higher rates of stress-related disorders, alcoholism, car accidents, and suicide. Men are more likely than women to be the victims of homicide. In sum, gender role expectations for men are hazardous to their health.
- *Relationships between men and women*. Too often, gender role expectations propose that men should be dominant, powerful, and aggressive and should control women. "Real men," according to many traditional definitions of masculinity, look at women in terms of their bodies, not their minds and feelings, have little interest in rapport talk and relationships, and do not consider women equal to men in work or many other aspects of life. Thus, traditional gender role expectations encourage men to disparage women, be violent toward women, and refuse to have equal relationships with women.
- *Relationships between men*. Too many men have had too little interaction with their fathers, especially fathers who are positive role models. Nurturing and being sensitive to others have been considered aspects of the traditional gender role for women but not for men. And the gender role expectations for men emphasize competition rather than cooperation. All of these aspects of the gender role expectations for men have left men with inadequate positive, emotional connections with other men.

To reconstruct their masculinity in more positive ways, Ron Levant (2001) suggests that every man should (1) reexamine his beliefs about manhood, (2) separate out the valuable aspects of gender role expectations, and (3) get rid of parts of the masculine role that are destructive. All of these processes involve becoming more "emotionally intelligent"—that is, becoming more emotionally self-aware, managing emotions more effectively, reading emotions better (one's own emotions and those of others), and being motivated to improve close relationships.

Gender and Aging Do our gender roles change when we become older adults? Some developmentalists maintain there is decreasing femininity in women and decreasing masculinity in men when they reach late adulthood (Gutmann, 1975). The evidence suggests that older men do become more *feminine*—nurturant, sensitive, and so on—but it appears that older women do not necessarily become more *masculine*—assertive, dominant, and so on (Turner, 1982). A longitudinal study revealed that as men entered their sixties, they endorsed more feminine items on a list of personal characteristics and therefore were more likely to be classified as *androgynous* (combination of masculine and feminine traits) (Hyde, Krajnik, & Skuldt-Niederberger, 1991).

developmental **connection**
Culture
Aging presents special challenges for ethnic minority individuals. Connect to "Peers and the Sociocultural World."

In a more recent cross-sectional study of individuals from 12 to 80 years and older, men in their seventies were more likely than adolescents and younger men to endorse androgynous traits (Strough & others, 2007). In the same study, women in their eighties and older were less likely than younger and middle-aged women to endorse masculine and androgynous traits. And in an even more recent study, among older adult men, those who were married were more likely to endorse stereotypically masculine traits but also to have higher androgyny scores than unmarried older men (Lemaster, Delaney, & Strough, 2017).

The studies of age differences we have just discussed were cross-sectional in nature and may reflect cohort effects. Keep in mind that cohort effects are especially important to consider in areas such as gender roles. As sociohistorical changes take place, what were once perceived to be age effects may turn out to be cohort effects (Schaie, 2016). For example, in the study described above (Strough & others, 2007), the early-adult and middle-aged women were "baby boomers," likely influenced by the women's movement as they were growing up and developing their identity. However, the oldest-old women likely had already established their gender identity when the women's movement began, which might explain why they were less likely than younger women to endorse masculine and androgynous traits.

A possible double jeopardy also faces many older women—the burden of both ageism and sexism (Goldblatt & others, 2021). In developing countries, the poverty rate for older adult women is almost double that for older adult men.

Not only is it important to be concerned about older women's double jeopardy of ageism and sexism, but special attention also needs to be devoted to ethnic minority older adult women (Angel, Mudrazija, & Benson, 2016). Many, but not all, immigrant ethnic groups traditionally have relegated the woman's role to family maintenance. Many important decisions may be made by a woman's husband or parents, and she is often not expected to seek an independent career or enter the workforce unless the family is in dire financial need.

Some ethnic minority groups may define an older woman's role as unimportant, especially if she is unable to contribute financially. However, in some ethnic minority groups, a woman's social status improves in later life. For example, older African American women can express their own needs and have status and power in the community. Despite their positive status in the African American family and the African American culture, however, African American women over the age of 70 are the poorest population group in the United States. Three of five older African American women live alone; most of them are widowed. The low incomes of older African American women translate into less than adequate access to health care. Substantially lower incomes for African American older women are related to the kinds of jobs they have held. Frequently these jobs are not covered by Social Security or, in the case of domestic service, the incomes of these women are not reported even when reporting is legally required.

A portrayal of older African American women in cities reveals some of their survival strategies. They highly value the family as a source of mutual support and aid, adhere to the American work ethic, and view religion as a source of strength (Proulx & others, 2020).

In sum, older African American women have faced considerable stress throughout their lives (Angel, Mudrazija, & Benson, 2016). In dealing with this stress, they have shown remarkable adaptiveness, resilience, responsibility, and coping skills. However, many older African American women would benefit considerably from improved support.

A special concern is the stress faced by African American elderly women. *What are some ways they cope with stress?*

4 Exploring Sexuality

LG4 Characterize influences on sexuality, the nature of sexual orientation, and some sexual problems.

- Biological and Cultural Factors
- Sexual Orientation
- Sexually Transmitted Infections
- Forcible Sexual Behavior and Sexual Harassment

Now that we have studied the gender aspects of being female or male, let's turn our attention to the sexual aspects. To explore sexuality, we examine biological and cultural factors, sexual orientation, sexually transmitted infections, and forcible sexual behavior and sexual harassment.

BIOLOGICAL AND CULTURAL FACTORS

We don't need sex for everyday survival the way we need food and water, but we do need it for the survival of the species. With this important role of sex in mind, let's examine how both biological and cultural factors are involved in sexuality (Nimbi & others, 2020).

Biological Factors In our earlier discussion of sexual development, we identified two main classes of sex hormones: estrogens (which primarily promote the development of female physical sex characteristics) and androgens (which mainly promote the development of male physical sex characteristics). The pituitary gland in the brain monitors hormone levels but is itself regulated by the hypothalamus. The pituitary gland sends out a signal to the testes or ovaries to manufacture a hormone; then the pituitary gland, through interaction with the hypothalamus, detects when the optimal level of the hormone is reached and maintains this level (Gurung, Yetiskul, & Jialal, 2021).

As our focus of attention moves from lower to higher animals, the role of hormones becomes less clear, especially in females. For human males, higher androgen levels are associated with sexual motivation and orgasm frequency. Nonetheless, sexual behavior is so individualized in humans that it is difficult to distinguish the effects of hormones.

Cultural Factors Sexual motivation also is influenced by cultural factors (Crooks & Bauer, 2021). The range of sexual values across cultures is substantial (Nimbi & others, 2020). Some cultures consider sexual pleasures "weird" or "abnormal." Consider the people who live on the small island of Inis Beag off the coast of Ireland. They are some of the most sexually repressed people in the world. They know nothing about tongue kissing or hand stimulation of the penis, and they detest nudity. For both females and males, premarital sex is out of the question (Messinger, 1971).

In contrast, consider the Mangaian culture in the South Pacific. In Mangaia, young boys are taught about masturbation and are encouraged to engage in it as much as they like. At age 13, the boys undergo a ritual that initiates them into sexual manhood. First, their elders instruct them about sexual strategies, including how to help their female partner have orgasms. Then, two weeks later, the boy has intercourse with an experienced woman who helps him hold back ejaculation until she can achieve orgasm with him. By the end of adolescence, Mangaians have sex virtually every day.

As reflected in the behavior of the people in these two different cultures, our sexual motivation is influenced by **sexual scripts** (Willie & others, 2018). These are stereotyped patterns of expectations for how people should behave sexually (Schuster, Tomaszewska, & Krahe, 2021). Two well-known sexual scripts are the traditional religious script and the romantic script. In the **traditional religious script,** sex is acceptable only within marriage. Extramarital sex is taboo, especially for women. Sex involves reproduction and sometimes affection. In the **romantic script,** sex is synonymous with love. If we develop a relationship with someone and fall in love, it is acceptable to have sex with that person within or outside of marriage.

You probably are familiar with some gender differences in sexual scripts (Thompson & others, 2020). Women tend to link sexual intercourse with love more than men do, and men are more likely to emphasize sexual conquest. Some sexual scripts involve a double standard; for example, it is okay for adolescent boys to have sex but not females, and if the girl gets pregnant it's viewed as her fault for not using contraception (Tolman & Chmielewski, 2019). One study of young adult men found two main sexual scripts: (1) a traditional "player" script for men, and (2) a script that emphasized mutual sexual pleasure (Morrison & others, 2014).

sexual scripts Stereotyped patterns of expectations for how people should behave sexually.

traditional religious script View that sex is acceptable only within marriage; extramarital sex is taboo, especially for women; and sex means reproduction and sometimes affection.

romantic script A perspective in which sex is synonymous with love; the belief that if we develop a relationship with someone and fall in love, it is acceptable to have sex with the person whether we are married or not.

Also, a recent international study of young adolescents in fourteen sites spanning four continents found consistent evidence for a sexual script of boys' social gains for having girlfriends and girls' risk for having boyfriends (Moreau & others, 2018).

SEXUAL ORIENTATION

A national study of sexual behavior in the United States among adults 25 to 44 years of age found that 98 percent of the women and 97 percent of the men said that they had ever engaged in vaginal intercourse (Chandra & others, 2011). Also in this study, 89 percent of the women and 90 percent of the men reported that they had ever had oral sex with an opposite-sex partner, and 36 percent of the women and 44 percent of the men stated that they had ever had anal sex with an opposite-sex partner.

More extensive information about adult sexual patterns comes from the 1994 Sex in America survey. In this well-designed, comprehensive study of American adults' sexual patterns, Robert Michael and his colleagues (1994) interviewed more than 3,000 people from 18 to 59 years of age who were randomly selected, a sharp contrast from earlier samples that consisted of unrepresentative groups of volunteers.

Heterosexual Attitudes and Behavior Here are some of the key findings from the 1994 Sex in America survey:

- Americans tend to fall into three categories: One-third have sex twice a week or more, one-third a few times a month, and one-third a few times a year or not at all. Married (and cohabiting) couples have sex more often than noncohabiting couples.
- Most Americans do not engage in non-traditional sexual acts. When asked about their favorite sexual acts, the vast majority (96 percent) said that vaginal sex was "very" or "somewhat" appealing. Oral sex was in third place, after an activity that many have not labeled a sexual act—watching a partner undress.
- Adultery is clearly the exception rather than the rule. Nearly 75 percent of the married men and 85 percent of the married women in the survey indicated that they had never been unfaithful.
- Men think about sex far more often than women do—54 percent of the men said they thought about it every day or several times a day, whereas 67 percent of the women said they thought about it only a few times a week or a few times a month.

In sum, one of the most powerful messages in the 1994 survey was that Americans' sexual lives are more conservative than was previously believed. Although 17 percent of the men and 3 percent of the women reported having had sex with at least 21 partners, the overall impression from the survey was that sexual behavior is ruled by marriage and monogamy for most Americans.

How extensive are gender differences in sexuality? A meta-analysis revealed that men reported having slightly more sexual experiences and more permissive attitudes than women regarding most aspects of sexuality (Peterson & Hyde, 2010). For the following factors, stronger differences were found: Men said that they engaged more often in masturbation, pornography use, and casual sex, and they expressed more permissive attitudes about casual sex than their female counterparts did.

Also, a national U.S. study found that 30.9 percent of men and 19.1 percent of women 18 to 24 years of age reported having been sexually inactive in the past year (Ueda & others, 2020). In this study, the proportions of sexually inactive people 25 to 34 years old (14.1 percent for men, 12.6 percent for women) and 35 to 44 years old (8.0 percent and 8.5 percent) were lower than the proportions of sexually active people in the 18- to 24-year-old category and percentagewise more similar among men and women. Further, sexual inactivity increased among men age 18 to 24 and age 25 to 34 from 2000 to 2018, and sexual inactivity increased across the same time period for women 25 to 34 years of age. The increased inactivity for men occurred mainly among those who were unmarried. Also, men with lower incomes and men who were working part-time or unemployed were more likely to be sexually inactive than men who had higher incomes and were employed full-time, as were women and men who were students. Among the reasons for decreased rates of sexual activity may be increased feelings of being stressed and overwhelmed in everyday life with which work and intimate relationships must compete. In addition, the extensive array of online entertainment available may interfere with sexual activity.

bisexuality Romantic or sexual attraction to more than one gender.

However, given all the media and public attention directed toward the negative aspects of sexuality—such as adolescent pregnancy, sexually transmitted infections, rape, and so on—it is important to underscore that research strongly supports the role of sexuality in well-being (Brody, 2010; King, 2020, 2022). For example, in a Swedish study frequency of sexual intercourse was strongly linked to life satisfaction for both women and men (Brody & Costa, 2009). And in a recent study, sexual activity in adults on day 1 was linked to greater well-being the next day (Kashdan & others, 2018). Also in this study, higher reported sexual pleasure and intimacy predicted more positive affect and less negative affect the next day.

Sexual Orientation Until the end of the nineteenth century, it was generally believed that people were either heterosexual or homosexual (an outdated term meaning same-gender sexual orientation). Today, sexual orientation is viewed less as an either/or proposition than as a continuum from exclusive different-gender orientation to exclusive same-gender orientation (Hyde & DeLamater, 2020). Some individuals have a sexual orientation along the continuum that represents attraction to more than one gender; these individuals might use terms such as *bisexual* (romantically or sexually attracted to people of more than one gender), *pansexual* (romantically or sexual attracted to all genders), and others.

There are some who believe that bisexuality is simply a steppingstone to same-gender sexual relationships, while others view it as a sexual orientation itself or as an indicator of sexual fluidity (King, 2020). Evidence supports the notion that for most people who feel this way, **bisexuality** is a stable orientation that involves attraction to more than one gender (King, 2020, 2022; Mock & Eibach, 2012).

Compared with men, women are more likely to change their sexual patterns and desires (Knight & Morales Hope, 2012). Women are more likely than men to have sexual experiences with same- and different-gendered partners, even if they identify themselves strongly as being heterosexual or lesbian (King, 2020, 2022). Also, women are more likely than men to identify themselves as bisexual (Gates, 2011).

In the Sex in America survey, 2.7 percent of the men and 1.3 percent of the women reported having had same-sex relations in the past year (Michael & others, 1994). However, in a national survey a higher percentage (3.8 percent) of U.S. adults reported that they were gay, lesbian, bisexual, or transsexual (Gallup, 2015). And in the most recent national survey of sexual orientation that included men and women from 18 to 44 years of age, 17.4 percent of women reported having had same-sex contact in their lifetime, compared with 6.2 percent of men (Copen, Chandra, & Febo-Vazquez, 2016). Feelings of attraction only toward the opposite sex were more frequent for men (92.1 percent) than for women (81 percent). Also in this study, 92.3 percent of the women and 95.1 percent of the men said they were heterosexual or straight. Further, 1.3 percent of women and 1.9 percent of men said they were homosexual, gay, or lesbian, and 5.5 percent of women and 2 percent of men reported that they were bisexual.

What likely determines whether a male or female has a same-sex orientation?
Creatas/Getty Images

Why are some individuals lesbian, gay, or bisexual (that is, sexual minority) and others heterosexual? Speculation on this topic has been extensive. All people, regardless of their sexual orientation, have similar physiological responses during sexual arousal and seem to be aroused by the same types of tactile stimulation. Investigators typically find no differences between sexual minority and heterosexual individuals in a wide range of attitudes, behaviors, and adjustments (Fingerhut & Peplau, 2013).

Recently, researchers have explored the possible biological basis of same-gender sexual relations. The results of hormone studies have been inconsistent. If gay men are given male sex hormones (androgens), their sexual orientation doesn't change. Their sexual desire merely increases. A very early prenatal critical period might cause an individual of any gender to later become attracted to men (Bogaert & Skorska, 2020). In the second to fifth months after conception, exposure of the fetus to hormone levels characteristic of females might cause the individual (male or female) to become attracted to males (Ellis & Ames, 1987). If this critical-period hypothesis turns out to be correct, it would explain why clinicians have found that sexual orientation is difficult, if not impossible, to modify.

Researchers have also examined genetic influences on sexual orientation by studying twins. A Swedish study of almost 4,000 twins found that only about 35 percent of the variation in same-gender sexual behavior in men and 19 percent in women could be explained by genetic differences (Langstrom & others, 2010). This result suggests that although genes likely play a role in sexual orientation, they are not the only influence.

An individual's sexual orientation is most likely determined by a combination of genetic, hormonal, cognitive, and environmental factors (Herdt & Polen-Petit, 2021). Most experts believe that no single factor accounts for sexual orientation and that the relative weight of each factor can vary from one individual to the next. That said, it has become clear that no matter whether a person is heterosexual, gay, lesbian, or bisexual, that individual cannot be talked out of his or her sexual orientation (King, 2020).

Attitudes and Behavior in Same-Gender Relationships Many gender differences that appear in heterosexual relationships also occur in same-gender relationships (Diamond, 2019). For example, lesbian women have fewer sexual partners than gay men, and lesbian women have less permissive attitudes about casual sex outside a primary relationship than gay men do (Fingerhut & Peplau, 2013). Also, a special concern is the discrimination and prejudice encountered by sexual minority individuals (Cahill & others, 2020). In a recent study, sexual minority reports of past-year general discrimination, victimization, and health care discrimination peaked in early adulthood and also in middle adulthood (Rice & others, 2021).

SEXUALLY TRANSMITTED INFECTIONS

Sexually transmitted infections (STIs) are diseases that are primarily contracted through penile-vaginal intercourse as well as oral-genital and anal-genital sex. STIs affect about one of every six U.S. adults (National Center for Health Statistics, 2021). Among the most prevalent STIs are bacterial infections—such as gonorrhea, syphilis, and chlamydia—and STIs caused by viruses—such as AIDS (acquired immune deficiency syndrome), genital herpes, and genital warts. Figure 3 describes these sexually transmitted infections.

sexually transmitted infections (STIs) Diseases that are contracted primarily through sexual contact, including oral-genital contact, anal-genital contact, and vaginal intercourse.

STI	Description/cause	Incidence	Treatment
Gonorrhea	Commonly called the "drip" or "clap." Caused by the bacterium *Neisseria gonorrhoeae*. Spread by contact between infected moist membranes (genital, oral-genital, or anal-genital) of two individuals. Characterized by discharge from penis or vagina and painful urination. Can lead to infertility.	500,000 cases annually in U.S.	Penicillin, other antibiotics
Syphilis	Caused by the bacterium *Treponema pallidum*. Characterized by the appearance of a sore where syphilis entered the body. The sore can be on the external genitals, vagina, or anus. Later, a skin rash breaks out on palms of hands and bottom of feet. If not treated, can eventually lead to paralysis or even death.	100,000 cases annually in U.S.	Penicillin
Chlamydia	A common STI named for the bacterium *Chlamydia trachomatis*, an organism that spreads by sexual contact and infects the genital organs of both sexes. A special concern is that females with chlamydia may become infertile. It is recommended that adolescent and young adult females have an annual screening for this STI.	About 3 million people in U.S. annually.	Antibiotics
Genital herpes	Caused by a family of viruses with different strains. Involves an eruption of sores and blisters. Spread by sexual contact.	One of five U.S. adults	No known cure but antiviral medications can shorten outbreaks
AIDS	Caused by a virus, the human immunodeficiency virus (HIV), which destroys the body's immune system. Semen and blood are the main vehicles of transmission. Common symptoms include fevers, night sweats, weight loss, chronic fatigue, and swollen lymph nodes.	More than 300,000 cumulative cases of HIV virus in U.S. 25–34-year-olds; epidemic incidence in sub-Saharan countries	New treatments have slowed the progression from HIV to AIDS; no cure
Genital warts	Caused by the human papillomavirus, which does not always produce symptoms. Usually appear as small, hard, painless bumps in the vaginal area or around the anus. Very contagious. Certain high-risk types of this virus cause cervical cancer and other genital cancers. May recur despite treatment. A new HPV preventive vaccine, Gardasil, has been approved for girls and women 9–26 years of age.	About 5.5 million new cases annually; considered the most common STI in the U.S.	A topical drug, freezing, or surgery

FIGURE **3**

A concern in the United States is the recent increase in STIs (Feltman, 2018). Especially concerning are the increased rates of gonorrhea, syphilis, and chlamydia in 2016 and again in 2017 (Centers for Disease Control and Prevention, 2018). Compared with 2013, gonorrhea diagnoses increased 67 percent and syphilis cases increased 76 percent in 2017. It is especially problematic that gonorrhea is increasingly resistant to antibiotic treatments.

No single disease has had a greater impact on sexual behavior or created more public fear in the last several decades than infection with the human immunodeficiency virus (HIV) (Yarber & Sayed, 2019). HIV is a virus that destroys the body's immune system. Once a person is infected with HIV, the virus breaks down and overpowers the immune system, which leads to AIDS (acquired immunodeficiency syndrome). An individual sick with AIDS has such a weakened immune system that a common cold can be life-threatening.

In 2018, 1.2 million people in the United States were living with an HIV infection (HIV.gov, 2020). Of this total, 1 in 7 were unaware of their HIV infection. In 2018, approximately 36,400 new HIV infections were diagnosed in the United States (HIV.gov, 2020). In 2018, sexual contact between two men continued to be the most frequent AIDS transmission category, accounting for 69 percent of new HIV infections (HIV.gov, 2020). Because of education and the development of more effective drug treatments, deaths due to HIV/AIDS have begun to decline in the United States. Also, there is an increasing effort to reduce HIV infections through pre-exposure prophylaxis (PrEP) awareness, which involves taking a daily pill that can reduce the probability of getting HIV by as much as 90 percent (Moskowitz & others, 2021).

A 13-year-old boy pushes his friends around in his barrow during a break from his work as a barrow boy in a sub-Saharan African community. He became the breadwinner in the family after both of his parents died of AIDS.
Louise Gubb/Corbis Historical/Getty Images

Globally, the number of AIDS-related deaths is decreasing, with 690,000 people dying from the disease in 2019 (down from a peak of 1.9 million in 2004) (UNAIDS, 2020). This decrease is attributed to the increased availability of antiretroviral therapy. The biggest decrease in AIDS-related deaths is occurring in sub-Saharan Africa. However, 1.7 million people worldwide acquired HIV in 2019 (UNAIDS, 2020).

What are some good strategies for avoiding HIV and other sexually transmitted infections? They include the following:

- *Knowing your own and your partner's risk status.* Anyone who has had previous sexual activity with another person might have contracted an STI without being aware of it. Spend time getting to know a prospective partner before you have sex. Use this time to inform the other person of your STI status and inquire about your partner's. Remember that many people lie about their STI status.
- *Obtaining medical examinations.* Many experts recommend that couples who want to begin a sexual relationship have a medical checkup to rule out STIs before they engage in sex. If cost is an issue, contact your campus health service or a public health clinic.
- *Having protected, not unprotected, sex.* When used correctly, latex condoms and dental dams help to prevent many STIs from being transmitted. Condoms and dental dams are most effective in preventing gonorrhea, syphilis, chlamydia, and HIV. They are less effective against the spread of herpes.
- *Not having sex with multiple partners.* One of the best predictors of getting an STI is having sex with multiple partners. Having more than one sex partner elevates the likelihood that you will encounter an infected partner.

FORCIBLE SEXUAL BEHAVIOR AND SEXUAL HARASSMENT

Too often, sex involves the exercise of power. Here we briefly look at three of the problems that may result: two types of rape and sexual harassment.

Rape

Rape is forcible sexual intercourse with a person who does not give consent. Legal definitions of rape differ from state to state. For example, in some states, husbands are not prohibited from forcing their wives to have intercourse, although this has been challenged in several of those states.

Because victims may be reluctant to suffer the consequences of reporting rape, the actual number of incidents is not easily determined (Koss & others, 2021). A meta-analysis found that 60 percent of rape victims do not acknowledge that they have been raped, with the percentage of unacknowledged rapes especially high in college students (Wilson & Miller, 2016).

Rape occurs most often in large cities, where it has been reported that 8 of every 10,000 women 12 years and older are raped each year. Nearly 200,000 rapes are reported each year in the United States. Although most victims of rape are women, rape of men does occur (Anderson & others, 2021). A study of college women who had been raped revealed that only 11.5 percent of them reported the rape to authorities, and of those in which the rape involved drugs and/or alcohol, only 2.7 percent of the rapes were reported (Wolitzky-Taylor & others, 2011). Men in prisons are especially vulnerable to rape, usually by heterosexual males who use rape as a means of establishing their dominance and power (Downer & Trestman, 2016).

A national study found that 7.4 percent of U.S. ninth- through twelfth-grade students reported that they had been physically forced to have intercourse against their will (Kann & others, 2018). In this study, approximately 11.3 percent of female students and 3.5 of male students reported having been forced to have sexual intercourse.

Why does rape of females occur so often in the United States? Among the causes given are that males are socialized to be sexually aggressive, to regard women as inferior beings, and to view their own pleasure as the most important objective in sexual relations (Tarzia, 2021). Researchers have found that male rapists share the following characteristics: aggression enhances their sense of power or masculinity; they are angry at women in general; and they want to hurt and humiliate their victims (Yarber & Sayed, 2019). Also, rape is more likely to occur when one or both individuals are drinking alcohol (Koss & others, 2021).

Rape is a traumatic experience for the victims and those close to them (Bragesjo & others, 2020; Farahi & McEachern, 2021). As victims strive to get their lives back to normal, they may experience depression, posttraumatic stress disorder, fear, anxiety, increased substance use, and suicidal thoughts for months or years (Basile & others, 2021). Sexual dysfunctions, such as reduced sexual desire and an inability to reach orgasm, occur in 50 percent of rape victims who are women (Sprei & Courtois, 1988). Recovery depends on the victim's coping abilities, psychological adjustments prior to the assault, and social support (Koss & others, 2021). Parents, a partner, and others close to the victim can provide important support for recovery, as can mental health professionals (Shannonhouse, Hill, & Hightower, 2021).

Date or acquaintance rape is coercive sexual activity directed at someone with whom the victim is at least casually acquainted (McDaniel & Rodriguez, 2021; Rerick, Livingston, & Davis, 2020). About two-thirds of college men admit that they fondle women against their will, and half admit to forcing sexual activity. Also, in a recent study, more than 87 percent of alcohol-involved sexual assault on college campuses was committed by serial perpetrators (Foubert, Clark-Taylor, & Wall, 2020). In this study, fraternity men and student athletes were more likely to commit alcohol-involved sexual assault than other men on campus. And a recent study found that women who had experienced sexual assault in college were subsequently more likely to have a lower grade point average, miss more classes, and have fewer serious romantic relationships while in college (Rothman & others, 2021). Also in this study, nine years later, women who had experienced sexual assault in college were more likely to report having symptoms of depression, anxiety, and post-traumatic stress. A number of colleges and universities have identified a "red zone"—a period of time early in the first year of college when women are at especially high risk for unwanted sexual experiences (Gray, Hassija, & Steinmetz, 2017). One study revealed that first-year women were at higher risk for unwanted sexual experiences, especially early in the fall term, than second-year women (Kimble & others, 2008). And in a recent study of college women who had experienced

rape Forcible sexual intercourse, oral sex, or anal sex with a person who does not give consent. Legal definitions of rape differ from state to state.

date or acquaintance rape Coercive sexual activity directed at someone with whom the victim is at least casually acquainted.

What are some characteristics of date or acquaintance rape?
Juanmonino/E+/Getty Images

acquaintance rape, 84 percent knew their perpetrator and 65.5 percent encountered their perpetrator after the attack (Bell, Wolff, & Skolnick, 2021). Women who encountered their perpetrator after the attack reported having more lifestyle changes and higher severity of posttraumatic stress disorder symptoms.

In an effort to reduce unwanted sexual experiences, the program "No Means No Worldwide" (https://nomeansnoworldwide.org) has been effective in reducing the incidence of sexual assault in the African countries of Kenya and Malawi (Baiocchi & others, 2017). The organization's 12-hour curriculum emphasizes interactive verbal skills, role playing, and other techniques to encourage people to speak up, prevent, or intervene in a sexual assault.

The personal autonomy and rights of individuals involving coercion in sexual experiences has recently produced a movement called *affirmative consent* on many college campuses. Affirmative consent means that instead of assuming that both partners are comfortable with sexual activity, each individual gives in words or actions an indication they are willing to participate in the sexual activity (Goodcase, Spencer, & Toews, 2021).

Sexual Harassment

Sexual harassment is a manifestation of power by one person over another. It takes many forms–from inappropriate sexual remarks and physical contact (patting, brushing against one's body) to blatant propositions and sexual assaults (Wolinetz, Lauer, & Collins, 2020). Millions of women experience sexual harassment each year in work and educational settings (Klein & Martin, 2021). Sexual harassment of men by women also occurs but to a far lesser extent than sexual harassment of women by men. In a recent study of young adults, women were more likely (37.4 percent) to report having experienced sexual harassment than men (22.4 percent) (Mumford & others, 2020).

In a survey of 2,000 college women, 62 percent reported having experienced sexual harassment while attending college (American Association of University Women, 2006). Most of the college women said that the sexual harassment involved noncontact forms such as crude jokes, remarks, and gestures. However, almost one-third said that the sexual harassment was physical in nature.

Sexual harassment can result in serious psychological consequences for the victim (Reuter & others, 2020). A study of almost 1,500 college women revealed that those who had been sexually harassed reported increased rates of psychological distress, physical illness, and disordered eating (Huerta & others, 2006).

Eliminating such exploitation requires improvements in work and academic environments (Rugulies & others, 2020). These types of improvements help to provide equal opportunities for people to develop a career and obtain an education in a climate free of sexual harassment

sexual harassment Sexual persecution that can take many forms—from sexist remarks and physical contact (patting, brushing against someone's body) to blatant propositions and sexual assaults.

UNITE TO FIGHT PATRIARCHY

What characterizes the Me Too Movement?
Faye Sadou/Media Punch Inc./Alamy Stock Photo

(Kahsay & others, 2020). In 2017, the Me Too Movement spread extensively, with "#MeToo" used as a hashtag on social media to show the prevalence of sexual assault and harassment of women, especially in the workplace. As a result, many women felt safe enough to openly discuss their experiences of sexual harassment after having remained silent about these experiences for years or even decades (Yecies & McNeil, 2021).

5 Sexuality Through the Life Span

LG5 Summarize how sexuality develops through the life span.

Childhood | Adolescence and Emerging Adulthood | Adult Development and Aging

So far we have discussed a number of aspects of human sexuality. Now, let's explore sexuality at different points in development, beginning with childhood.

CHILDHOOD

Most psychologists doubt Freud's claim that preschool children have a strong sexual attraction to the parent of the other sex. But what are some aspects of sexuality in children?

A majority of children engage in some sex play, usually with friends or siblings (Moore, 2019). Childhood sex play includes exhibiting or inspecting the genitals. Much of this sex play is likely motivated by curiosity. There does not appear to be any link between such sexual play and sexual adjustment in adolescence or adulthood.

As the elementary school years progress, sex play with others usually declines, although romantic interest in peers may be present. Curiosity about sex remains high throughout the elementary school years, and children may ask many questions about reproduction and sexuality. However, the main surge in sexual interest takes place not in childhood but in early adolescence (Herdt & Polen-Petit, 2021).

ADOLESCENCE AND EMERGING ADULTHOOD

Adolescence is a critical juncture in the development of sexuality as pubertal changes unfold and individuals develop a sexual identity (Hyde & DeLamater, 2020). And emerging adulthood provides further opportunities for individuals to explore the sexual aspects of their lives.

Adolescence Adolescence is a time of sexual exploration and experimentation, of sexual fantasies and realities, and of incorporating sexuality into one's identity. Adolescents have an almost insatiable curiosity about sexuality. They think about whether they are sexually attractive,

Sexual arousal emerges as a new phenomenon in adolescence, and it is important to view sexuality as a normal aspect of adolescent development.

—Shirley Feldman
Contemporary Psychologist, Stanford University

What characterizes the sexual culture U.S. adolescents are exposed to?
Jacob Lund/Shutterstock

how to engage in sex, and what the future holds for their sexual lives. The majority of adolescents eventually manage to develop a mature sexual identity, but most experience times of vulnerability and confusion (Crooks & Baur, 2021).

The Sexual Culture Adolescence is a bridge between the asexual child and the sexual adult (Herdt & Polen-Petit, 2021). Every society gives some attention to adolescent sexuality. In some societies, adults clamp down and protect adolescent females from males by chaperoning them. Other societies promote very early marriage. Yet others allow some sexual experimentation.

In the United States, children and adolescents learn a great deal about sex from the media. The messages come from TV commercials, which use sex to sell just about everything, as well as from the content of TV shows. A recent study of the prime-time shows that U.S. adolescents and emerging adults watch on television found that sexual violence and abuse, casual sex, lack of contraception use, and no coverage of the consequences of risky sexual behavior were common (Kinsler & others, 2019). Also, adolescent engagement in *sexting,* which involves sending sexually explicit images, videos, or text messages via electronic communication, has become increasingly common (Lee & Darcy, 2021). For example, in a recent national study of U.S. middle and high school students, 13 percent reported they had sent a sext and 18.5 percent indicated they had received a sext (Patchin & Hinduja, 2019). Further, a recent study of emerging adults found that receiving unwanted sexts and sexting under coercion were linked to higher levels of depression, anxiety, and stress, and lower self-esteem (Klettke & others, 2019).

Identity
Identity can be conceptualized in terms of identity statuses: diffused, foreclosed, moratorium, and achievement. Connect to "The Self, Identity, and Personality."

Developing a Sexual Identity Mastering emerging sexual feelings and forming a sense of sexual identity is a multifaceted and lengthy process (Diamond, 2019; Savin-Williams, 2019). It involves learning to manage sexual feelings (such as sexual arousal and attraction), developing new forms of intimacy, and learning the skills to regulate sexual behavior to avoid undesirable consequences. An adolescent's sexual identity is influenced by *social norms* related to sex—the extent to which adolescents perceive that their peers are having sex, using protection, and so on. These social norms have important influences on adolescents' sexual behavior. For example, one study revealed that when adolescents perceived that their peers were sexually permissive, the adolescents had a higher rate of initiating sexual intercourse and engaging in risky sexual practices (Potard, Courtois, & Rusch, 2008). An individual's sexual identity also can be linked to other developing identities, which are discussed in the chapter on "The Self, Identity, and Personality."

An adolescent's sexual identity involves activities, interests, styles of behavior, and an indication of sexual orientation (the gender to which an individual is attracted) (Carroll, 2019). For example, some adolescents have a high anxiety level about sex, others a low level. Some adolescents are strongly aroused sexually, others less so. Some adolescents are very active sexually, others not at all. Some adolescents are sexually inactive in response to their strong religious upbringing, while others attend church regularly but their religious training does not inhibit their sexual activity.

Ritch Savin-Williams (2019) and Lisa Diamond (2019) have conducted in-depth research and analyses of the development of sexual minority adolescents. It is commonly believed that most *sexual minority* individuals (gay, lesbian, or other non-heterosexual orientations) quietly struggle with same-gender attractions in childhood, do not engage in heterosexual dating, and gradually recognize that they are sexual minority in mid- to late adolescence (Savin-Williams, 2019). Many youth do follow this developmental pathway, but others do not. For example, many youth have no recollection of same-gender attractions in childhood and experience a more abrupt awareness of their same-gender attraction in late adolescence. Researchers also have found that the majority of adolescents with same-gender attractions also experience some

degree of attraction to a different gender (Diamond, 2019). Even though some adolescents who are attracted to same-gender individuals fall in love with these individuals, others claim that their same-gender attractions are purely physical (Savin-Williams, 2019). In the timing and sequence of sexual developmental milestones, there are few individual differences between heterosexual and sexual minority adolescents except that sexual minority adolescents have to cope with their sexual identity in more stressful ways, including disclosing their sexual identity to family members (Savin-Williams, 2019).

In sum, sexual minority youth have diverse patterns of initial attraction, often have attractions to more than one gender, and may feel physical or emotional attraction to same-gender individuals but do not always fall in love with them (Diamond, 2019; Savin-Williams, 2019). Further, the majority of sexual minority adolescents have competent and successful paths of development through adolescence and become healthy and productive adults. However, in a large-scale study, sexual minority adolescents did engage in a higher prevalence of health-risk behaviors (drug use and sexual risk taking, for example) than heterosexual adolescents (Kann & others, 2016). And a recent study found that early sexual debut (first sexual intercourse before age 13) was associated with sexual risk taking, substance use, violent victimization, and suicidal thoughts/attempts in both sexual minority (in this study, gay, lesbian, or bisexual adolescents) and heterosexual youth (Lowry & others, 2017).

What are some developmental pathways of same-sex attraction in adolescence?
Steve Edreff/Shutterstock

The Timing and Frequency of Adolescent Sexual Behaviors The timing of sexual initiation varies by country as well as by gender and other socioeconomic characteristics. In one cross-cultural study, among girls, the proportion having first intercourse by age 17 ranged from 72 percent in Mali to 47 percent in the United States and 45 percent in Tanzania (Singh & others, 2000). The percentage of boys who had their first intercourse by age 17 ranged from 76 percent in Jamaica to 64 percent in the United States and 63 percent in Brazil. Within the United States, adolescents who are male, African American, and live in the inner city report being the most sexually active, whereas Asian American adolescents have the most restrictive sexual timetable (Feldman, Turner, & Araujo, 1999).

What is the current profile of sexual activity among adolescents? In a U.S. national survey conducted in 2019, 38.4 percent of ninth- to twelfth-graders reported ever having had sexual intercourse (Underwood & others, 2020). Compared with earlier national figures, sexual intercourse in adolescence has been declining recently—in 1991, the national figure was 54.1 percent and in 2011 it was 47.4 percent. Nationally, in 2019, 56.7 percent of twelfth-graders, 46.5 percent of eleventh-graders, 33.6 percent of tenth-graders, and 19.2 percent of ninth-graders reported that they ever had engaged in sexual intercourse. According to a recent estimate by the National Survey of Family Growth, the probability of having sexual intercourse in the United States by age 20 was 77 percent for males and 79 percent for females (Martinez & Abma, 2020).

Age at sexual initiation varies by ethnic group in the United States (Underwood & others, 2020). In the 2019 U.S. survey of ninth- to twelfth-graders, 42.3 percent of African Americans, 42.3 percent of Latinxs, 38 percent of non-Latinx Whites, and 15.6 percent of Asian Americans said they had experienced sexual intercourse (Underwood & others, 2020). The African American percentage has especially been dropping in recent years—it was 49 percent in 2015. Also, in this study, 3 percent of U.S. adolescents reported that their first sexual experience took place before 13 years of age—down from 6.2 percent in 2011 and 10.2 percent in 1991 (Underwood & others, 2020). Further in this study, 6.9 percent of African American high school students (compared with 33.8 percent of Latinxs, 1.9 percent of non-Latinx Whites, and 0.8 percent of

developmental **connection**
Biological Processes
Girls enter puberty approximately two years earlier than boys, with pubertal change peaking on average at age 11½ in girls and 13½ in boys. Connect to "Physical Development and Biological Aging."

Asian Americans) reported having had their first sexual experience before 13 years of age. In sum, these figures represent significantly decreased rates in recent years of having sexual intercourse during adolescence or prior to age 13.

Recent research indicates that oral sex is now a common occurrence among U.S. adolescents (Goldstein & Halpern-Felsher, 2018). In a recent national survey of more than 7,000 15- to 24-year-olds, 58.6 percent of the girls reported ever having performed oral sex and 60.4 percent said they had ever received oral sex (Holway & Hernandez, 2018). Also, in another national survey, 51 percent of U.S. 15- to 19-year-old boys and 47 percent of girls in the same age group said they had engaged in oral sex (Child Trends, 2015). Thus, more youth engage in oral sex than vaginal sex, likely because they perceive oral sex to be more acceptable and to be associated with fewer health risks.

One study also found that among adolescent girls who reported having vaginal sex first, 31 percent reported having a teen pregnancy, whereas among those who initiated oral-genital sex first, only 8 percent reported having a teen pregnancy (Reese & others, 2013). Thus, how adolescents initiate their sex lives may have positive or negative consequences for their sexual health.

What are some risks associated with early initiation of sexual intercourse?
Stockbyte/Punchstock/Getty Images

Sexual Risk Factors in Adolescence Many adolescents are not emotionally prepared to handle sexual experiences, especially in early adolescence (Evans & others, 2020). Early sexual activity is linked with risky behaviors such as drug use, delinquency, and school-related problems (Clark & others, 2021; Vashishtha & others, 2021). In a study of Korean adolescent girls, early menarche was linked to earlier initiation of sexual intercourse (Kim & others, 2017). Another study confirmed that early engagement in sexual intercourse (prior to 14 years of age) is associated with high-risk sexual factors (forced sex, using drugs/alcohol at last sex, not using a condom at last sex, having multiple partners in the previous month, and becoming pregnant or causing a pregnancy), as well as experiencing dating violence (Kaplan & others, 2013). Also, a study of more than 3,000 Swedish adolescents revealed that sexual intercourse before age 14 was linked to risky behaviors such as an increased number of sexual partners, experience of oral and anal sex, negative health behaviors (smoking, drug and alcohol use), and antisocial behavior (being violent, stealing, running away from home) at 18 years of age (Kastbom & others, 2015). Further, a recent South African study found that early sexual debut predicted a lower probability of graduating from high school (Bengesai, Khan, & Dube, 2018). And in an Australian study, sex at age 15 or younger predicted higher rates of emerging adult (average age 21) pregnancy, lifetime sexual partners, and sex without using a condom (Prendergast & others, 2019). In this study, early sex also was associated with higher rates of emerging adult substance use and antisocial behavior.

Substance abuse, especially in early adolescence, is linked to sexual risk practices (Ahuja & others, 2021). For example, in a recent study, the likelihood of initiating sexual intercourse before age 13 was higher among individuals who engaged in substance abuse and had mental health problems (Okumu & others, 2019).

A number of family factors are associated with sexual risk taking (Messer & others, 2021). In a recent study of adolescents, spending more high-quality time with parents was linked to a lower likelihood of engaging in vaginal sex, anal sex, oral sex, pornography access, and masturbation (Astle, Leonhardt, & Willoughby, 2020). Also, one study revealed that adolescents who in the eighth grade reported greater parental knowledge of their activities and more family rules about dating were less likely to initiate sex as eighth- through tenth-graders (Ethier & others, 2016). In another study, difficulties and disagreements between Latinx adolescents and their parents were linked to the adolescents' early sexual initiation (Cordova & others, 2014). Another study revealed that among a number of parenting practices, the factor that best predicted a lower level of risky sexual behavior by adolescents was supportive parenting (Simons & others, 2016). Also, having older sexually active siblings or pregnant/parenting teenage sisters placed adolescent girls at increased risk for pregnancy (Miller, Benson, & Galbraith, 2001). Further, in a recent study of urban, predominantly Latinx and African American adolescents, talk with extended family members about sexual protection was linked to adolescents having fewer sexual partners, while talk about risks involved in sex was associated with adolescents having more sexual partners (Grossman & others, 2019).

Socioeconomic status/poverty, peer, school, sports, and religious contexts provide further information about sexual risk taking in adolescents (Warner, 2018). The percentage of sexually

active young adolescents is higher in low-income areas of inner cities (Morrison-Beedy & others, 2013). One study found that associating with more deviant peers in early adolescence was related to having more sexual partners at age 16 (Lansford & others, 2010). A recent study revealed that associating with antisocial peers predicted early engagement in sexual intercourse (Clark & others, 2021). Further, a research review found that school connectedness was linked to positive sexuality outcomes (Markham & others, 2010). Further, one study found that adolescent girls who skipped school or failed a test were more likely to frequently have sexual intercourse and less likely to use contraceptives (Hensel & Sorge, 2014). Another study found that adolescent boys who play sports engage in a higher level of sexual risk taking, while adolescent girls who play sports engage in a lower level of sexual risk taking (Lipowski & others, 2016). And a recent study of African American adolescent girls indicated that those who reported that religion was of low or moderate importance to them had a much earlier sexual debut than their counterparts who said that religion was very or extremely important to them (George Dalmida & others, 2018).

Cognitive and personality factors are increasingly implicated in sexual risk taking in adolescence. Two such factors are self-control and impulsiveness. A recent study confirmed that low self-control is linked to reducing risky sexual behavior in adolescence (Magnusson, Crandall, & Evans, 2020).

Contraceptive Use Sexual intercourse is a normal activity necessary for procreation, but if appropriate safeguards are not taken it brings the risk of unintended pregnancy and sexually transmitted infections (Herdt & Polen-Petit, 2021). Both of these risks can be reduced significantly by using certain forms of contraception, especially condoms (Williams & others, 2021).

A recent national study revealed a substantial increase in the use of contraceptives by U.S. high school students the last time they had sexual intercourse (54.4 percent in 2019 versus 46 percent in 1991 but down from 60 percent in 2011) (Szucs & others, 2020). Also, younger adolescents are less likely to take contraceptive precautions than are older adolescents. In this national study, 23.2 percent of African American, 12.8 percent of Latinx, and 6.8 percent of non-Latinx White sexually active adolescents reported using no pregnancy prevention (Szucs & others, 2020).

Recently, a number of leading medical organizations and experts have recommended that adolescents use long-acting reversible contraception (LARC) (Menon & the Committee on Adolescence, 2020). These organizations include the Society for Adolescent Health and Medicine (2017) and the World Health Organization (2021). LARC consists of the use of intrauterine devices (IUDs) and contraceptive implants, which have a much lower failure rate and greater effectiveness in preventing unwanted pregnancy than the use of birth control pills and condoms (Grubb & the Committee on Adolescence, 2020; Lanzola & Ketvertis, 2021). A recent national study found that adolescent use of long-acting reversible contraception (LARC) increased from 1.8 percent in 2013 to 5.3 percent in 2017 (Aligne & others, 2020). And in another study, LARC use increased from 2010 to 2017, although urban, educated, and higher-income women were more likely than adolescents to use LARC (Beshar & others, 2021).

Sexually Transmitted Infections Earlier, we described sexually transmitted infections. Here we focus on their incidence among adolescents. Nearly half of the 20 million new STI infections in the United States occur in 15- to 24-year-olds (Kann & others, 2018). In 2018, the 13- to 24-year-old age group made up 21 percent of the 37,832 new HIV diagnoses in the United States (Centers for Disease Control and Prevention, 2020). Of these youth, 44.9 percent were living with an undiagnosed HIV infection in 2018—a higher percentage than any other age group. Most of the new diagnoses involved young gay and bisexual males—male-to-male transmission made up 92 percent of these new diagnoses. In terms of ethnicity, 51 percent were African American, 27 percent Latinx, and 17 non-Latinx White individuals.

As we discussed earlier, a special concern is the high incidence of AIDS in sub-Saharan Africa (UNAIDS, 2020). In 2019, sub-Saharan Africa accounted for 88 percent of children and adolescents living with AIDS worldwide (UNAIDS, 2020). Adolescent girls in many African countries are vulnerable to being infected with HIV by adult men. Far more adolescent girls than boys have AIDS in these countries, whereas in the United States adolescent boys are more likely to have AIDS than adolescent girls (UNAIDS, 2020). In Kenya, 25 percent of 15- to 19-year-old girls are HIV-positive, compared with 4 percent of boys.

Sixteen-year-old Alberto's maternal grandmother was a heroin addict who died of cancer at 40. His father, just 17 when Alberto was born, has been in prison most of Alberto's life. His mother and stepfather are not married but have lived together for a dozen years and have four other children. Alberto's stepbrother dropped out of school when he was 17, fathered a child, and is unemployed. But Alberto, who lives in the Bronx in New York City, has different plans for his own future. He says he wants to be a dentist "like the kind of woman who fixed his teeth at Bronx-Lebanon Hospital Center clinic when he was a child" (Bernstein, 2004, p. A22). And Alberto, along with his girlfriend, Jasmine, wants to remain a virgin until he is married.
Suzanne DeChillo/The New York Times/Redux Pictures

Adolescent Pregnancy Unintended pregnancy is another problematic outcome of sexuality in adolescence and requires major efforts to reduce its occurrence (Messer & others, 2021; Wong & others, 2020). In cross-cultural comparisons, the United States continues to have one of the highest adolescent pregnancy and childbearing rates in the industrialized world, despite a considerable decline in the 1990s (Cooksey, 2009). The adolescent pregnancy rate is four times higher in the United States than it is in the Netherlands (Sedgh & others, 2015). This dramatic difference exists in spite of the fact that U.S. adolescents are no more sexually active than their counterparts in the Netherlands. A cross-cultural comparison found that among 21 countries, the United States had the highest adolescent pregnancy rate among 15- to 19-year-olds and Switzerland had the lowest rate (Sedgh & others, 2015).

Despite the negative comparisons of the United States with many other developed countries, there have been some encouraging trends in U.S. adolescent pregnancy rates. In 2019, the U.S. birth rate for 15- to 19-year-olds was 16.7 births per 1,000 females, the lowest rate ever recorded, and less than half the rate in 2008 (41.5 births per 1,000 females) (Martin & others, 2021) (see Figure 4). There also has been a substantial decrease in adolescent pregnancies across ethnic groups in recent years. Reasons for the decline include school/community health classes, increased contraceptive use, and fear of sexually transmitted infections such as AIDS.

Ethnic variations characterize adolescent pregnancy. For 15- to 19-year-old U.S. females in 2017, per 1,000 females the birth rate for Latinxs was 25.3 (down from 38 in 2014), for African Americans 25.8 (down from 35 in 2014), for non-Latinx Whites 11.4 (down from 17 in 2014), and for Asian Americans 2.7 (down from 8 in 2014) (Martin & others, 2021). These figures represent substantial decreases in adolescent pregnancy rates for Latinx and African American teens, especially for Latinx and African American adolescent girls However, Latinx and African American girls are more likely to have a second child during adolescence than are non-Latinx adolescent girls (Rosengard, 2009). And daughters of teenage mothers are at higher risk for teenage childbearing, thus perpetuating an intergenerational cycle. A study using data from the National Longitudinal Survey of Youth revealed that daughters of teenage mothers were 66 percent more likely to become teenage mothers themselves (Meade, Kershaw, & Ickovics, 2008).

developmental **connection**

Culture

The high school dropout rate for Latinx adolescents is higher than for any other ethnic group, except Native American adolescents. Connect to "Schools, Achievement, and Work."

The consequences of America's high adolescent pregnancy rate are cause for great concern (Asheer & others, 2020). Adolescent pregnancy creates health and developmental outcome risks for both the baby and the mother (Kumar & Huang, 2021). Infants born to adolescent mothers are more likely to have low birth weights—a prominent factor in infant mortality—as well as neurological problems and childhood illness (Leftwich & Alves, 2017; Sawyer, Abdul-Razak, & Patton, 2019). One study assessed the reading and math achievement trajectories of children born to adolescent and non-adolescent mothers with different levels of education (Tang & others, 2016). In this study, higher levels of maternal education were linked to higher levels of academic achievement through the eighth grade. Nonetheless, the achievement of children born to adolescent mothers never reached the levels of children born to adult mothers.

What are some of the problems that characterize adolescent mothers? In a recent Canadian study, 18 percent of adolescent mothers lived in low-SES neighborhoods (compared to 11 percent of mothers 20 to 34 years of age), had higher rates of depression during pregnancy, and also had higher rates of tobacco, marijuana, and alcohol use than adult mothers (Wong & others, 2020). In addition, adolescent mothers are more likely to be depressed and drop out of school than their peers (Leftwich & Alves, 2017; Phipps & others, 2020).

A special concern is repeated adolescent pregnancy. In a recent national study, the percentage of teen births that were repeat births decreased from 21 percent in 2004 to 17 percent in 2015 (Dee & others, 2017). In a recent meta-analysis, use of effective contraception, especially LARC, and education-related factors (higher level of education and school continuation) resulted in a lower incidence of repeated teen pregnancy, while depression and a history of abortion were linked to a higher percentage of repeated teen pregnancy (Maravilla & others, 2017).

connecting with careers

Lynn Blankinship, Family and Consumer Science Educator

Lynn Blankinship is a family and consumer science educator. She has an undergraduate degree in her specialty from the University of Arizona and has taught for more than 20 years, the last 14 at Tucson High Magnet School.

Blankinship received the Tucson Federation of Teachers Educator of the Year Award for 1999–2000 and was honored in 1999 as the Arizona Association of Family and Consumer Science Teacher of the Year.

Blankinship especially enjoys teaching life skills to adolescents. One of her favorite activities is having students care for an automated baby that imitates the needs of real babies. She says that this program has a profound impact on students because the baby must be cared for around the clock for the duration of the assignment. Blankinship also coordinates real-world work experiences and training for students in several child-care facilities in the Tucson area.

Lynn Blankinship (*center*) with students carrying their automated babies.
Lynn Blankinship

For more information about what family and consumer science educators do, see the Careers in Life-Span Development appendix.

Researchers have found that adolescent mothers interact less effectively with their infants than do adult mothers. One study revealed that adolescent mothers spent more time in negative interactions and less time in play and positive interactions with their infants than did adult mothers (Riva Crugnola & others, 2014). One intervention, "My Baby and Me," that involved frequent (55), intensive home visitation coaching sessions with adolescent mothers across three years resulted in improved maternal behavior and child outcomes (Guttentag & others, 2014).

Although the consequences of America's high adolescent pregnancy rate are cause for great concern, it often is not pregnancy alone that leads to negative consequences for an adolescent mother and her offspring. As indicated earlier, adolescent mothers are more likely to come from low-SES backgrounds (Joyner, 2009). Many adolescent mothers also were not good students before they became pregnant (Malamitsi-Puchner & Boutsikou, 2006). However, not every adolescent girl who bears a child lives a life of poverty and low achievement. Thus, although adolescent pregnancy is a high-risk circumstance and adolescents who do not become pregnant generally fare better than those who do, some adolescent mothers do well in school and have positive outcomes (Schaffer & others, 2012).

All adolescents can benefit from comprehensive sexuality education, beginning prior to adolescence and continuing through adolescence (Herdt & Polen-Petit, 2021). Family and consumer science educators teach life skills, such as effective decision making, to adolescents. To read about the work of one family and consumer science educator, see the *Connecting with Careers* profile. And to learn more about ways to reduce adolescent pregnancy, see the *Connecting Development to Life* interlude.

Emerging Adulthood At the beginning of emerging adulthood (age 18), surveys indicate that slightly more than 60 percent of individuals have experienced sexual intercourse, but by the end of emerging adulthood (age 25), most individuals have had sexual intercourse (Wesche & Lefkowitz, 2020). Also, the U.S. average age for a first marriage had climbed to 30.1 years for men and 28.3 years for women in 2020, higher than at any other point in history (U.S. Census Bureau, 2020). Thus, emerging adulthood is a time frame during which most individuals are both sexually active and unmarried (Wesche & Lefkowitz, 2020). In a recent study, across the college years, rates of kissing, touching, performing and receiving

connecting development to life

Reducing Adolescent Pregnancy

Girls Inc (2021) has created programs that benefit adolescents at risk for problems. Their program focused on adolescent pregnancy provides girls with skills, motivation, and support to postpone sexual activity and use effective protection. In a recent analysis, girls who participated in the Girls Inc pregnancy prevention program were less likely to become pregnant (5.9 percent) than a matched control group of girls who did not participate in the program (12.3 percent) (Girls Inc, 2021).

Currently, a number of studies are being funded by the Teen Pregnancy Prevention (TPP) program in an effort to find ways to reduce the rate of adolescent pregnancy (Office of Adolescent Health, 2021). These diverse programs focus on such areas as improving adolescent self-control, developing a positive relationship with a trusted adult, delaying sexual initiation, and planning for a future that includes positive opportunities and outcomes.

Currently, a major controversy in sex education is whether schools should have an abstinence-only program or a comprehensive sex education program that emphasizes contraceptive knowledge, delaying sexual intercourse, and reducing the frequency of sex and number of partners (Garzon-Orjuela & others, 2021; Kantor & others, 2021; Wiley & others, 2020). A recent research review and analysis concluded that research across the last three decades provides strong support for comprehensive sex education across a range of topics and grade levels (Goldfarb & Lieberman, 2021). Further, recent research reviews have concluded that abstinence-only programs do not delay the initiation of sexual intercourse and do not reduce HIV risk behaviors (Santelli & others, 2017). Recently there has been an increased emphasis on abstinence-only-until-marriage (AOUM) policies and programs in many U.S. schools. However, a major problem with such policies and programs is that a very large majority of individuals engage in sexual intercourse at some point in adolescence or emerging adulthood, while the average age when people marry for the first time continues to go up (currently 27 for women, 29 for men in the United States). The Society for Adolescent Health and Medicine (2017) released a policy position noting that research evidence indicates that many comprehensive sex education programs successfully delay initiation of sexual intercourse and reduce rates of sexually transmitted infections. The Society's policy position also states that research indicates AOUM programs are ineffective in delaying sexual intercourse and reducing other sexual risk behaviors. Also, some sex-education programs are starting to include abstinence-plus sexuality by promoting abstinence as well as providing instructions for contraceptive use, although the effectiveness of these programs has not been fully evaluated (Barr & others, 2014).

A number of leading experts on adolescent sexuality now conclude that sex education programs that emphasize contraceptive knowledge do not increase the incidence of sexual intercourse and are more likely to reduce the risk of adolescent pregnancy and sexually transmitted infections than abstinence-only programs (Society for Adolescent Health and Medicine, 2017). What additional research might help expand the reach of such programs?

oral sex, and penetrative sex rates increased (Lefkowitz & others, 2019). Also in this study, contraceptive use decreased during the college years, especially for men and for students in serious romantic relationships.

Uncertainty characterizes many emerging adults' sexual relationships (Wesche & Lefkowitz, 2020). Consider a study of emerging adult daters and cohabitors that found nearly half reported a reconciliation (a breakup followed by a reunion) (Halpern-Meekin & others, 2013). Also, emerging adults report that on days when they have vaginal sex they have more positive affect; however, they report higher levels of negative affect or other negative consequences if they have sex with someone they are not dating (Vasilenko & Lefkowitz, 2018).

Casual sex is more common in emerging adulthood than it is during the late twenties (Wesche & Lefkowitz, 2020). A recent trend has involved "hooking up" to have non-relationship sex (from kissing to intercourse) (Sutton, Simons, & Tyler, 2021). In a recent analysis of first-year college students in six focus groups, a common theme they described was: "Sex is easier to get and love is harder to find" (Anders & others, 2020). Also, one study indicated that 40 percent of 22-year-olds reported having had a recent casual sexual partner (Lyons & others, 2015). Another study also revealed that 20 percent of first-year college women on one large university campus had engaged in at least one hookup over the course of the school year (Fielder & others, 2013). In this study, impulsivity, sensation seeking, and alcohol use were among the predictors of a higher likelihood of hooking up. Further, in a recent study, a greater percentage of emerging adult women than men reported having sex, hooking up with an acquaintance, using partner characteristics as a reason to hook up, and having negative reactions to their most recent hookup (Olmstead, Norona, & Anders, 2019). In this study, a greater

percentage of emerging adult men than women reported hooking up with a stranger, meeting at a bar/club, and hooking up at a party.

In addition to hooking up, another type of casual sex that has recently increased among emerging adults is "friends with benefits" (FWB), which involves a relationship formed by the integration of friendship and sexual intimacy without an explicit commitment characteristic of an exclusive romantic relationship (Weger, Cole, & Akbulut, 2019). A recent study found that suicidal ideation was associated with entrance into a friends with benefits relationship as well as continuation of the FWB relationship (Dube & others, 2017). Also, in a study of almost 8,000 emerging adults, men had more permissive sexual attitudes, especially regarding sexual encounters, than did women (Sprecher, Treger, & Sakaluk, 2013).

What are some characteristics of sexual patterns in emerging adulthood?
Onoky/SuperStock

ADULT DEVELOPMENT AND AGING

Earlier in our coverage of sexual orientation, we examined a number of basic ideas about heterosexual and sexual minority attitudes and behavior. Much of what we said there applied to young adults. Here we focus on changes in middle adulthood and late adulthood.

Middle Adulthood

What kinds of changes characterize the sexuality of women and men as they go through middle age? **Climacteric** is a term used to describe the midlife transition when fertility declines.

Menopause

Menopause is the time in middle age, usually during the late forties or early fifties, when an assigned female's menstrual periods cease (Peacock & Ketvertis, 2021). The average age at which U.S. assigned females have their last period is 51 (Mayo Clinic, 2021a). However, there is a large variation in the age at which menopause occurs–from 39 to 59 years of age. A recent Norwegian study of more than 300,000 women found that late menopause was associated with an increased risk of breast cancer (Gottschalk & others, 2020). In this study, the mean age of menopause increased 2½ years in recent decades to 52.7 years in Norway (Gottschalk & others, 2020).

The average age at menarche, first menstruation for an assigned female, has significantly decreased since the mid-nineteenth century, occurring as much as four years earlier in some countries (Susman & Dorn, 2013). Has there been a similar earlier onset in the occurrence of menopause? No, there hasn't been a corresponding change in menopause, and there is little or no correlation between the onset of menarche and the onset of menopause (Gosden, 2007). However, researchers have found that early-onset menopause is linked to a higher risk of cardiovascular disease and stroke (Kaur, Singh, & Ahula, 2012).

Perimenopause is the transitional period from normal menstrual periods to no menstrual periods at all, which often takes up to 10 years. Perimenopause occurs most often in the forties but can occur in the thirties (Raglan, Schulkin, & Micks, 2020). One study of 30- to 50-year-old women found that depressed feelings, headaches, moodiness, and heart palpitations were the perimenopausal symptoms that these women most frequently discussed with health-care providers (Lyndaker & Hulton, 2004). Lifestyle factors such as whether women are overweight, smoke, drink heavily, or exercise regularly during perimenopause influence aspects of their future health status such as whether they develop cardiovascular disease or chronic illnesses (Shorey, Ang, & Lau, 2020). A recent study found that the more minutes per week that women exercised during the menopausal transition, the lower their perceived stress was (Guerin & others, 2019).

In menopause, production of estrogen by the ovaries declines dramatically, and this decline produces uncomfortable symptoms in some women– "hot flashes," nausea, fatigue, and rapid heartbeat, for example (Santoro & others, 2021).

Cross-cultural studies also reveal wide variations in the menopause experience (Rathnayake & others, 2018). For example, hot flashes are uncommon in Mayan women (Beyene, 1986). Asian women report fewer hot flashes than women in Western societies (Payer, 1991). In a recent study in China, Mosuo women (Mosuo is a matriarchal tribe in southern China where women have the dominant role in society, don't marry, and can take on as many lovers as they desire) had fewer negative menopausal symptoms, higher self-esteem, and better family support than Han Chinese women (the majority ethnic group in China) (Zhang & others, 2019). It is difficult to determine the extent to which these cross-cultural variations are due to genetic, dietary, reproductive, or cultural factors.

climacteric The midlife transition when fertility declines.

menopause The complete cessation of a female's menstrual cycles, which usually occurs during the late forties or early fifties.

perimenopause The transitional period from normal menstrual periods to no menstrual periods at all, which often takes up to 10 years.

Menopause overall is not the negative experience for most women that it was once thought to be (Brown & others, 2018). Most women do not have severe physical or psychological problems related to menopause. For example, a research review concluded that there is no clear evidence that depressive disorders occur more often during menopause than at other times in a woman's reproductive life (Judd, Hickey, & Bryant, 2012).

However, the loss of fertility is an important marker for women—it means that they have to make final decisions about having children. Women in their thirties who have never had children sometimes mention being "up against the biological clock" because they cannot postpone choices about having children much longer.

Until recently, hormone replacement therapy was often prescribed as a treatment for unpleasant side effects of menopause. Hormone replacement therapy (HRT) augments the declining levels of reproductive hormone production by the ovaries (Devi, Creatura, & Devi-Chou, 2020; Langer & others, 2021). HRT can consist of various forms of estrogen, usually in combination with a progestin.

The National Institutes of Health recommends that women who have not had a hysterectomy and who are currently taking hormones consult with their doctor to determine whether they should continue the treatment. If they are taking HRT for short-term relief of menopausal symptoms, the benefits may outweigh the risks. HRT also lowers the risk of bone loss and bone fractures in post-menopausal women (de Villiers & others, 2016). Also, research indicates that if women take HRT within 10 years following menopause, it is associated with reduced risk of coronary heart disease (Langer, 2017). However, research indicates that hormone replacement therapy is linked to a slightly higher risk of breast cancer and the longer HRT is taken, the greater the risk of breast cancer (American Cancer Society, 2021; Breastcancer.org, 2021). The current consensus is that HRT increases the risk of breast cancer in women (Breastcancer.org, 2021).

Many middle-aged women are seeking alternatives to HRT such as regular exercise, mindfulness training, dietary supplements, herbal remedies, relaxation therapy, acupuncture, hypnosis, and nonsteroidal medications (Morardpour & others, 2020). One study revealed that in sedentary women, aerobic training for six months decreased menopausal symptoms, especially night sweats, mood swings, and irritability (Moilanen & others, 2012). Another study found that yoga improved the quality of life of menopausal women (Reed & others, 2014). And in a recent analysis of research, it was concluded that mindfulness training is linked to improved psychological adjustment during the menopause transition (Molefi-Youri, 2019).

Suzie Ross/McGraw Hill

Hormonal Changes in Middle-Aged Men Do assigned males go through anything like the menopause that assigned females experience? In other words, is there a male menopause? During middle adulthood, most men do not lose their capacity to father children, although there usually is a modest decline in their sexual hormone level and activity (Abootalebi & others, 2020). Men experience hormonal changes in their fifties and sixties, but nothing like the dramatic drop in estrogen that women experience. Testosterone production begins to decline about 1 percent a year during middle adulthood, and sperm count usually shows a slow decline, but men do not lose their fertility in middle age. The term *male hypogonadism* is used to describe a condition in which the body does not produce enough testosterone (Mayo Clinic, 2021b). What has been referred to as "male menopause," then, may have less to do with hormonal change than with the psychological adjustment men must make when they are faced with declining physical energy and with family and work pressures.

The gradual decline in men's testosterone levels in middle age can reduce their sexual drive (Goel & others, 2009). Their erections are less full and less frequent, and men require more stimulation to achieve them. Researchers once attributed these changes to psychological factors, but increasingly they find that as many as 75 percent of the erectile dysfunctions in middle-aged men stem from physiological problems. Smoking, diabetes, cardiovascular issues, depression, and lack of exercise are linked to many erectile problems in middle-aged men (Crafa & others, 2020).

Recently, there has been a dramatic surge of interest in *testosterone replacement therapy (TRT)* (Barbonetti, D'Andrea, & Francavilla, 2020; Khodamoradi & others, 2021). Recent research indicates that TRT can improve sexual functioning, muscle strength, and bone health in men with low testosterone levels (Mayo Clinic, 2021b). A recent study indicated that TRT-related benefits in quality of life and sexual function were maintained for 36 months after

initial treatment (Rosen & others, 2017). Also, a recent research review concluded that TRT improves sexual function in men who have hypogonadism, although positive data on other outcomes, such as cardiovascular disease, are inconclusive (Corona, Torres, & Maggi, 2020). Men who have prostate cancer or breast cancer should not take TRT, and men who are at risk for blood clotting (those who have atrial fibrillation, for example) also may need to avoid TRT (Osterberg, Bernie, & Ramasamy, 2014).

Erectile dysfunction (ED) is a common condition in aging men, affecting approximately 50 percent of men 40 to 70 years of age (Mola, 2015). Low testosterone can cause erectile dysfunction (Garcia-Cruz & Alcaraz, 2020). Treatment for men with erectile dysfunction has focused on the drug Viagra and on similar drugs, such as Levitra and Cialis (Ma & others, 2020; Smith & Babos, 2021). Viagra works by allowing increased blood flow into the penis, which produces an erection. Its success rate is in the 60 to 85 percent range (Claes & others, 2010).

How frequently do middle-aged U.S. adults engage in sexual intercourse?
Kristy-Anne Glubish/Design Pics

Low-intensity shockwave therapy, which also has been used in wound healing and musculoskeletal disorders, has recently been used for treating ED (Adeldaheim & others, 2021). A recent research review concluded that low-intensity shockwave therapy shows benefits in reducing ED after 6 months of treatment and ongoing but lesser benefits at 1 year, with results weaker overall for older adults (Brunckhorst & others, 2019). In addition, a recent study found that a combined treatment of low-intensity shockwave therapy and Cialis was superior to Cialis alone in reducing ED (Verze & others, 2020). However, too few studies of the efficacy of this therapy have been conducted to draw conclusions at this time about its effectiveness.

Sexual Attitudes and Behavior

Although the ability of men and women to function sexually shows little biological decline in middle adulthood, sexual activity usually occurs on a less frequent basis than in early adulthood (Hyde & DeLamater, 2020). Career interests, family matters, decreased energy levels, and routine may contribute to this decline (Avis & others, 2009). Nonetheless, with recent advances in erectile dysfunction medications such as Viagra, an increasing number of older men, especially the young-old, are able to have an erection (Lei & others, 2021). In a recent study, higher frequency of sexual activity in middle-aged and older adults also was linked to better overall cognitive functioning, especially in working memory and executive function (Wright, Jenks, & Demeyere, 2019).

Living with a spouse or partner makes all the difference in whether people engage in sexual activity, especially for women over 40 years of age. In one study conducted as part of the Midlife in the United States Study (MIDUS), 95 percent of women in their forties with partners said that they had been sexually active in the last six months, compared with only 53 percent of those without partners (Brim, 1999). By their fifties, 88 percent of women living with a partner had been sexually active in the last six months, but only 37 percent of those who were neither married nor living with someone reported having had sex in the last six months.

A person's health in middle age is a key factor in sexual activity during this period (Field & others, 2013). A study of adults 55 years and older revealed that their level of sexual activity was associated with their physical and mental health (Bach & others, 2013). Social and relationship factors also are important influences on sexual functioning during middle age. For example, in a recent study of healthy middle-aged women, interpersonal aspects such as emotional support and relationship satisfaction, as well the personality traits of optimism and self-esteem, were key predictors of the quality of sexual functioning (Memone, Fiacco, & Ehlert, 2019). Also, in a recent study, increased sexual satisfaction in middle-aged and older women was associated with a lower number of physical illnesses, better self-rated health, absence of depression, and higher importance of sexuality and intimacy (Buczak-Stec, Konig, & Hajek, 2021). Also in this study, greater sexual satisfaction was linked to having a partner, living with a partner, and being less lonely.

What are some characteristics of sexuality in older adults? How does sexual activity change as older adults go through the late adulthood period?
Image Source/Getty Images

Late Adulthood

Too often it has been assumed that older adults do not have sexual desires. Aging does induce some changes in human sexual performance, more so in men than in women, but many older adults do have sexual desires (Wright, Jenks, & Demeyere, 2019). Orgasm becomes less frequent in males,

occurring in every second to third act of intercourse rather than every time. More direct stimulation usually is needed to produce an erection. From 65 to 80 years of age, approximately one out of four men has serious problems getting or keeping erections; for those over 80 years of age, the percentage rises to one out of two men (Butler & Lewis, 2002). Even when intercourse is impaired by infirmity, other relationship needs persist, among them closeness, sensuality, and being valued as a man or a woman.

In a recent national study, 65- to 80-year-olds were asked about their sexual activity and sexual health (University of Michigan, 2018). In this study, 40 percent indicated they currently were sexually active, with sexual activity decreasing with age (46 percent age 65 to 70, 39 percent age 71 to 75, and 25 percent age 76 to 80). Men were more likely to report being sexually active (51 percent) than women (31 percent). Sixty-five percent indicated they were interested in sex and 73 percent said they were satisfied with their sex life. Almost 20 percent of men and 3 percent of women reported that they had taken medication or supplements to improve their sexual functioning. Also, a higher percentage of men indicated they were extremely or very interested in sex (50 percent) compared with women (12 percent) and a higher percentage of men (70 percent) than women (40 percent) reported that sex was important to their quality of life.

In other research on sexual behavior in older adults, engaging in sexual activity was linked to greater enjoyment of life (Smith & others, 2019). Also, in another study, older adults were asked about their motivation for having sex (Gewirtz-Meydan & Ayalon, 2019). In this study, five main reasons for having sex were (1) to maintain their functioning; (2) to feel young again; (3) to feel attractive and desirable; (4) to go from lust to love; and (5) to change from "getting sex" to "giving sex."

Review *Connect* Reflect

LG5 Summarize how sexuality develops through the life span.

Review

- What is the nature of childhood sexuality?
- How do adolescents develop a sexual identity? How does sexual behavior develop?
- What are some risk factors for sexual problems during adolescence?
- What are some patterns of behavior for emerging adults?
- How does sexuality change in middle adulthood? How does sexuality change in late adulthood?

Gender and Sexuality

1 Biological, Social, and Cognitive Influences on Gender

LG1 Explain biological, social, and cognitive influences on gender.

Biological Influences

- Gender refers to the characteristics of people as boys/men and girls/women. Key aspects of gender include gender roles and gender-typing (the process by which children acquire the thoughts, feelings, and behaviors that are considered appropriate for their gender).

Social Influences

- Biological influences on sex include heredity, hormones, and evolution. A 23rd pair of chromosomes with two X-shaped chromosomes produces a female; a 23rd pair with an X and a Y chromosome produces a male. Estrogens primarily influence the development of female physical sex characteristics and help regulate the menstrual cycle. Androgens primarily promote the development of male genitals and secondary sex characteristics. Evolutionary psychology argues that adaptation during the evolution of humans produced psychological differences between males and females.
- Three theories have been influential in arguing that psychological differences between the genders are due to social factors. Social role theory states that gender differences result from the contrasting roles of women and men. The psychoanalytic theory of gender stems from Freud's view that the preschool child develops a sexual attraction to the opposite-gender parent, then at 5 or 6 years of age renounces the attraction because of anxious feelings, subsequently identifies with the same-gender parent and unconsciously adopts the characteristics of the same-gender parent. The social cognitive theory of gender states that children learn about gender through observation and imitation and through reward and punishment for gender-appropriate and gender-inappropriate behavior. Parents, other adults, the media, and peers influence children's gender development.

Cognitive Influences

- Gender schema theory states that gender-typing emerges as children gradually develop gender schemas of what is gender-appropriate and gender-inappropriate in their culture.

2 Gender Stereotypes, Similarities, Differences, and Classification

LG2 Discuss gender stereotypes, similarities, differences, and classification.

Gender Stereotyping

- Gender stereotypes are general impressions and beliefs about boys/men and girls/women. Gender stereotypes are widespread.

Sex and Gender Similarities and Differences

- There are a number of physical differences between males and females, small or nonexistent cognitive differences, and some socioemotional differences (boys/men are more physically aggressive and active, but engage in less emotional self-regulation; girls/women show a stronger interest in relationships; girls are more people-oriented and boys are more object-oriented).
- Controversy surrounds how extensive gender differences are and what causes the differences. Gender in context is an important concept—gender behavior often varies across contexts, not only within a particular culture but also across cultures.

Gender-Role Classification

- Gender-role classification focuses on the degree to which individuals are masculine, feminine, or androgynous. Androgyny means having positive feminine and masculine characteristics. Recently, considerable interest has been generated about the gender category of transgender, which refers to individuals who adopt a gender identity that differs from the one assigned to them at birth. Given the complexity and variety of gender identity categories, the overarching umbrella term *trans* has been proposed.

Going Beyond Gender as Binary

- The traditional conceptualization of gender as being binary (having only two categories: boys/men and girls/women) is being challenged. These challenges occur in neuroscience, where human brains are described more as a mosaic than as "his or her" brains; in endocrinology, where research reveals more hormonal similarities in males and females than used to be thought; in the use of an increasing number of gender identity categories, including transgender and nonbinary; and in developmental research, which reveals that the gender worlds of boys/men and girls/women are not only due to biological factors but are culturally influenced and malleable. Also, gender categories are not mutually exclusive and can change over time.

3 Gender Development Through the Life Span

LG3 Describe the development of gender through the life span.

Childhood

- Children form many ideas about what girls/women and boys/men are like from about 1½ to 3 years of age. The amount, timing, and intensity of gender socialization differ for girls and boys. Boys receive earlier and more intense gender socialization than girls do.

Adolescence

- During early adolescence, girls and boys must come to terms with new definitions of their gender roles as they experience the extensive changes of puberty. There is continued controversy about whether all young adolescents experience gender intensification.

Adulthood and Aging

- Many experts argue that it is important for women to retain their relationship strengths but also to put more energy into self-development. Tannen stresses that many women prefer rapport talk and many men prefer report talk. Men have been successful at achieving career goals, but typical gender role expectations for men involve considerable strain. There is diversity in men's experiences, just as there is in women's. Men seem to become more nurturant and sensitive when they get older, but there is mixed evidence about whether women tend to become more assertive and dominant as they get older.

4 Exploring Sexuality

LG4 Characterize influences on sexuality, the nature of sexual orientation, and some sexual problems.

Biological and Cultural Factors

- The role of hormones in human sexual behavior is difficult to define. Sexual motivation is also influenced by cultural factors. Sexual scripts in cultures influence sexual behavior. In some sexual scripts, women link sexual intercourse with love more than do men, women are blamed if they become pregnant, and men tend to emphasize sexual conquest.

Sexual Orientation

- An individual's sexual orientation likely is the result of a combination of genetic, hormonal, cognitive, and environmental factors. In the 1994 Sex in America survey, Americans' sexual lives were reported to be more conservative than in earlier surveys.
- Sexual orientation is generally viewed as a continuum. Regardless of sexual orientation, most people emphasize the importance of trust, affection, and shared interests in a relationship.

Sexually Transmitted Infections

- Sexually transmitted infections (STIs) are contracted primarily through sexual contact. The STI that has received the most attention in recent years is HIV. Gonorrhea, syphilis, chlamydia, genital herpes, and HPV are among the most common STIs. Some good strategies for protecting against STIs include knowing your own and your partner's risk status; obtaining screening for STIs; avoiding unprotected sex; and not having sex with multiple partners.

Forcible Sexual Behavior and Sexual Harassment

- Rape is forcible sexual intercourse, oral sex, or anal sex with a person who does not give consent. Rape usually produces traumatic reactions in its victims. Sexual harassment occurs when one person uses his or her power over another individual in a sexual manner.

5 Sexuality Through the Life Span

LG5 Summarize how sexuality develops through the life span.

Childhood

- A majority of children engage in some sex play, usually with siblings or friends. Their motivation is probably mainly curiosity, and there does not appear to be a link between childhood sex play and adolescent or adult sexual adjustment.

Adolescence and Emerging Adulthood

- Adolescence is a time of sexual exploration and sexual experimentation. Mastering emerging sexual feelings and forming a sense of sexual identity are two challenges of this period.
- Sexual minority youth have diverse patterns of initial attraction, often have attractions to more than one gender, and may experience same-gender emotional or physical attractions.
- National U.S. data indicate that by age 19, four out of five individuals have had sexual intercourse. A dramatic increase in oral sex has occurred among adolescents, although many adolescents are unaware of the health risks associated with oral sex.
- Risk factors for sexual problems include early sexual activity, engaging in delinquency and excessive drinking, living in a low-SES neighborhood, ineffective parenting, and having an older sibling who engages in sex.
- Contraceptive use by adolescents is increasing. About one in four sexually experienced adolescents acquires a sexually transmitted infection (STI). The adolescent pregnancy rate in the United States is high but has been decreasing in recent years.
- Emerging adults have sexual intercourse less frequently than young adults do; emerging adult men have more casual sexual partners and are less selective than emerging adult women in their partner choice; and by the end of emerging adulthood, most people have had sexual intercourse.

Adult Development and Aging

- Menopause usually occurs during the late forties or early fifties. Perimenopause, the transition from normal menstrual periods to no menstrual periods at all, often takes up to 10 years.

- Hormone replacement therapy (HRT) augments the declining levels of reproductive hormone production by the ovaries. HRT consists of various forms of estrogen and usually progestin. Research has shown that HRT has benefits for many women in reducing menopausal symptoms, bone loss, bone fractures, and coronary heart disease. However, HRT is associated with increased rates of breast cancer.
- Men do not experience an inability to father children in middle age, although their testosterone level drops. In late adulthood, sexual changes do occur, more so for men than for women.

preview

Just as a person's emotional life and sexual life change with age, a person's moral life and spiritual life also develop through the life span. In this chapter we examine how moral development proceeds. We also explore how people go beyond questions of right and wrong to search for values, religion, spirituality, and meaning at different points in their lives.

1 Domains of Moral Development

LG1 Discuss theory and research on moral thought, behavior, feeling, personality, and domains.

- What Is Moral Development?
- Moral Thought
- Moral Behavior
- Moral Feeling
- Moral Personality
- Social Domain Theory

Moral development is a topic of great concern to societies, communities, and families because it involves how we get along with each other. It is also one of the oldest topics of interest to those who are curious about human nature. Philosophers and theologians have talked about it and written about it for many centuries. In the twentieth century, psychologists began theorizing about and studying moral development.

WHAT IS MORAL DEVELOPMENT?

Moral development involves changes in thoughts, feelings, and behaviors regarding standards of right and wrong. Moral development has an intrapersonal dimension, which involves a person's activities when she or he is not engaged in social interaction, and an *interpersonal* dimension, which regulates social interactions and arbitrates conflict. To understand moral development, we consider five basic questions:

- First, how do individuals reason or think about moral decisions?
- Second, how do individuals actually behave in situations requiring moral decision making?
- Third, how do individuals feel about moral matters?
- Fourth, what characterizes an individual's moral personality?
- Fifth, how is the moral domain different from social conventional and personal domains?

As we consider various theories and domains in the following sections, keep in mind that thoughts, behaviors, feelings, and personality often are interrelated. For example, if the focus is on an individual's behavior, it is still important to evaluate the person's reasoning. Also, emotions can influence moral reasoning. And moral personality encompasses thoughts, behavior, and feelings.

MORAL THOUGHT

How do individuals decide what is right and wrong? Are children able to evaluate moral questions in the same way that adults can? Jean Piaget had some thoughts about these questions. So did Lawrence Kohlberg.

Piaget's Theory

Interest in how children think about moral issues was stimulated by Piaget (1932), who extensively observed and interviewed children from the ages of 4 through 12. Piaget watched children play marbles to learn how they used and thought about the game's rules. He also asked children about ethical issues—theft, lies, punishment, and justice, for example. Piaget concluded that children go through two distinct stages in how they think about morality:

- From 4 to 7 years of age, children display **heteronomous morality,** the first stage of moral development in Piaget's theory. Children who are in this stage of moral development think of justice and rules as unchangeable properties of the world, removed from the control of people.

moral development Changes in thoughts, feelings, and behaviors regarding standards of right and wrong.

heteronomous morality The first stage of moral development in Piaget's theory, occurring at 4 to 7 years of age. Justice and rules are conceived of as unchangeable properties of the world, removed from the control of people.

Piaget extensively observed and interviewed 4- to 12-year-old children as they played games to learn how they used and thought about the games' rules.

developmental **connection**
Cognitive Theory
In which of Piaget's cognitive stages is a 5-year-old heteronomous thinker likely to be? Connect to "Cognitive Developmental Approaches."

How is this child's moral thinking likely to be different about stealing a cookie depending on whether he is in Piaget's heteronomous or autonomous stage?
Fuse/Getty Images

autonomous morality The second stage of moral development in Piaget's theory, displayed by children about 10 years of age and older. At this stage, children become aware that rules and laws are created by people and that in judging an action they should consider the actor's intentions as well as the consequences.

immanent justice Belief that if a rule is broken, punishment will be meted out immediately.

- From 7 to 10 years of age, children are in a transition showing some features of the first stage of moral reasoning and some features of the second stage, autonomous morality.
- From about 10 years of age onward, children show **autonomous morality**. They become aware that rules and laws are created by people, and in judging an action, they consider the actor's intentions as well as the consequences.

Because young children are heteronomous moralists, they judge the rightness or goodness of behavior by considering its consequences, not the intentions of the actor. For example, to the heteronomous moralist, breaking twelve cups accidentally is worse than breaking one cup intentionally. As children develop into moral autonomists, intentions assume paramount importance.

The heteronomous thinker also believes that rules are unchangeable and are handed down by all-powerful authorities. When Piaget suggested to young children that they use new rules in a game of marbles, they resisted. By contrast, older children—moral autonomists—accept change and recognize that rules are merely convenient conventions, subject to change.

The heteronomous thinker also believes in **immanent justice,** the concept that if a rule is broken, punishment will be meted out immediately. The young child believes that a violation is connected automatically to its punishment. Thus, young children often look around worriedly after doing something wrong, expecting inevitable punishment. Immanent justice also implies that if something unfortunate happens to someone, the person must have transgressed earlier. Older children, who are moral autonomists, recognize that punishment occurs only if someone witnesses the wrongdoing and that, even then, punishment is not inevitable.

How do these changes in moral reasoning occur? Piaget argued that as children develop, they become more sophisticated in thinking about social matters, especially about the possibilities and conditions of cooperation. Piaget stressed that this social understanding comes about through the mutual give-and-take of peer relations. In the peer group, where others have power and status similar to the child's, plans are negotiated and coordinated, and disagreements are reasoned about and eventually settled. Parent-child relations, in which parents have power and children do not, are less likely to advance moral reasoning, because rules are often handed down in an authoritarian way.

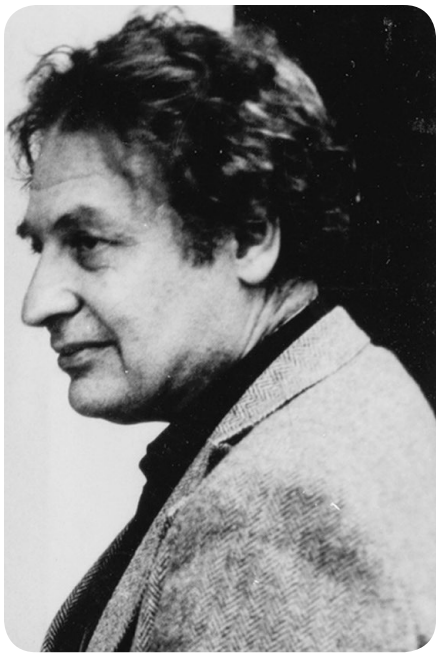
From Ross Thompson's perspective, young children are not as egocentric as Piaget envisioned. Thompson (2012) further elaborates on this view, arguing that recent research indicates that young children often show a non-egocentric awareness of others' goals, feelings, and desires and how such internal states are influenced by the actions of others. These ties between advances in moral understanding and theory of mind indicate that young children possess cognitive resources that allow them to be aware of others' intentions and know when someone violates a moral prohibition. One study of 3-year-olds found that they were less likely to offer assistance to an adult they had previously observed being harmful to another person (Vaish, Carpenter, & Tomasello, 2010).

However, because of limitations in their self-control skills, social understanding, and cognitive flexibility, young children's moral advancements often are inconsistent and vary across situations. They still have a long way to go before they have the capacity to develop a consistent moral character and make ethical judgments.

Kohlberg's Cognitive Developmental Theory A second major perspective on moral development was proposed by Lawrence Kohlberg (1958, 1986). Central to Kohlberg's work on moral development were interviews with individuals of different ages. In the interviews, individuals were presented with a series of stories in which characters face moral dilemmas. The following is the most cited of the Kohlberg dilemmas:

> In Europe, a woman was near death from a special kind of cancer. There was one drug that the doctors thought might save her. It was a form of radium that a druggist in the same town had recently discovered. The drug was expensive to make, but the druggist was charging ten times what the drug cost him to make. He paid $200 for the radium and charged $2,000 for a small dose of the drug. The sick woman's husband, Heinz, went to everyone he knew to borrow the money, but he could only get together $1,000, which is half of what it cost. He told the druggist that his wife was dying and asked him to sell it cheaper or let him pay later. But the druggist said, "No, I discovered the drug, and I am going to make money from it." So Heinz got desperate and broke into the man's store to steal the drug for his wife. (Kohlberg, 1969, p. 379)

This story is one of eleven that Kohlberg devised to investigate the nature of moral thought. After reading the story, interviewees are asked a series of questions about the moral dilemma: Should Heinz have stolen the drug? Was stealing it right or wrong? Why? Is it a husband's duty to steal the drug for his wife if he can get it no other way? Would a good husband steal it? Did the druggist have the right to charge that much when there was no law setting a limit on the price? Why or why not?



Lawrence Kohlberg.

Kohlberg's Three Levels From the answers interviewees gave for this and other moral dilemmas, Kohlberg identified three levels of moral development. A key concept in understanding progression through the levels is that people's morality becomes more mature. That is, their judgments of whether given behaviors are morally right or wrong begin to go beyond the superficial reasons they gave when they were younger to encompass more complex coordination of multiple perspectives.

- ***Kohlberg's Level 1: Preconventional Reasoning.*** **Preconventional reasoning** is the lowest level in Kohlberg's theory of moral development. At this level, moral reasoning is strongly influenced by external punishment or reward. For example, children and adolescents obey adults because they are afraid they will be punished. Or they decide to be obedient to get something out of it, such as a cookie. This earliest level of moral development has sometimes been described as "What's in it for me?"

  There is a much stronger punishment-and-obedience than reward orientation in Level 1 moral reasoning because children respect the power of adults. There also are adults at this level who adopt an "eye-for-an-eye" or "you scratch my back and I'll scratch yours" approach to moral reasoning.
- ***Kohlberg's Level 2: Conventional Reasoning.*** **Conventional reasoning** is the second, or intermediate, level in Kohlberg's theory of moral development. In conventional reasoning, individuals develop expectations about social roles.

  Level 2 comes into play when for the first time the naked self-pursuit of Level 1 now gives way to conventional expectations of good behavior within the society of friends and family. For example, in the story about Heinz and the druggist, wouldn't a good husband steal the drug to save his wife's life? In terms of obeying the laws of society, at Level 2 reasoning, individuals come to understand that for a community and nation to work effectively, they need to be protected by laws that everyone follows.
- ***Kohlberg's Level 3: Postconventional Reasoning.*** **Postconventional reasoning** is the highest level in Kohlberg's theory of moral development. In Level 3 reasoning, conventional considerations are now judged against moral concerns such as liberty, justice, and equality, with the idea that morality can improve the laws, fix them, and guide conventional institutions in the direction of a better world.

  At the highest point in Level 3, people are aware that moral principles make demands on them. Yes, Heinz should steal the drug because the value of life trumps the druggist's right to property. However, this moral judgment has a universal intent—everyone in Heinz's position should also steal the drug.

Kohlberg argued that these levels occur in a sequence and are age-related: Before age 9, most children reason about moral dilemmas in a preconventional way; by early adolescence, they reason in more conventional ways. By early adulthood, a small number of individuals reason in postconventional ways. In a 20-year longitudinal investigation, uses of Level 1 decreased (Colby & others, 1983).

Any change in moral reasoning between late adolescence and early adulthood appears to be relatively gradual and is enhanced by diverse social experiences (Narváez & Hill, 2010). One study found that when 16- to 19-year-olds and 18- to 25-year-olds were asked to reason about real-life moral dilemmas (in contrast with the usual focus on hypothetical dilemmas) and their responses were coded using Kohlberg's levels, there was no significant difference in the moral reasoning of the two age groups (Walker & others, 1995). So, even though people may be capable of higher moral reasoning, in real life they may not apply it.

Influences on the Development of Moral Judgment What factors influence movement through Kohlberg's stages? Although moral reasoning at each level presupposes a certain level of cognitive development, Kohlberg argued that maturation did not ensure advances in moral reasoning. Instead, the development of moral reasoning requires experience in dealing with moral questions and moral conflict.

preconventional reasoning The lowest level in Kohlberg's theory of moral development. The individual's moral reasoning is controlled primarily by a punishment-and-obedience orientation.

conventional reasoning The second, or intermediate, level in Kohlberg's theory of moral development. At this level, individuals develop expectations about social roles and an understanding of the need for laws in a society.

postconventional reasoning The highest level in Kohlberg's theory of moral development. At this level, conventional considerations are judged against moral concerns such as liberty, justice, and equality, with the idea that morality can improve laws.

Both Piaget and Kohlberg argued that peer relations are a critical part of the social stimulation that challenges children to advance their moral reasoning. The mutual give-and-take of peer relations provides children with role-taking opportunities that give them a sense that rules are generated democratically.
pankration/Getty Images

Several investigators have tried to advance individuals' levels of moral development by having a model present arguments that reflect moral thinking one level above each individual's current level. This approach applies the concepts of equilibrium and conflict that Piaget used to explain cognitive development. By presenting arguments slightly beyond the person's level of moral reasoning, the researchers created a disequilibrium that motivated the person to restructure his or her moral thought. The upshot of studies using this approach is that virtually any plus-level discussion, for any length of time, seems to promote more advanced moral reasoning (Walker, 1982).

Kohlberg noted that peer interaction is a critical part of the social stimulation that challenges children to change their moral reasoning. Whereas adults characteristically impose rules and regulations on children, the give-and-take among peers gives children an opportunity to take the perspective of another person and to generate rules democratically. Kohlberg stressed that in principle, encounters with any peers can produce perspective-taking opportunities that may advance a child's moral reasoning. In adolescence and emerging adulthood, diverse and intense experiences facilitate the development of moral reasoning (Rest & others, 1999).

Kohlberg's Critics

Kohlberg's theory has provoked debate, research, and criticism (Jambon & Smetana, 2020; Lapsley, 2020; Lapsley, LaPorte, & Kelley, 2022; Narváez, 2020; Spinrad & Eisenberg, 2020). Key criticisms involve the link between moral thought and moral behavior, controversy about whether moral reasoning is conscious/deliberative or unconscious/automatic, the role of emotion, the importance of gender, as well as the roles of culture and the family in moral development.

Moral Reasoning and Moral Behavior

Kohlberg's theory has been criticized for placing too much emphasis on moral reasoning and not enough emphasis on moral behavior (Walker, 2004). Moral reasons can sometimes be used as a shelter for immoral behavior. Corrupt CEOs and politicians endorse the loftiest of moral virtues in public before their own transgressions are exposed. Whatever the latest public scandal, you will probably find that the culprits displayed virtuous thoughts but engaged in immoral behavior. No one wants a nation of cheaters and thieves who can reason at the postconventional level. The cheaters and thieves may know what is right yet still do what is wrong. Heinous actions can be cloaked in a mantle of moral virtue.

Conscious/Deliberative Versus Unconscious/Automatic

Social psychologist Jonathan Haidt (2006, 2013, 2018) argues that in Kohlberg's theory, individuals spend too much time deliberating and contemplating in their reasoning before they decide on a stance. Haidt believes that moral thinking is more often an intuitive gut reaction, with deliberative moral reasoning serving as an after-the-fact justification. Thus, in his view, much of morality begins with rapid evaluative judgments of others rather than with strategic reasoning about moral circumstances (Graham & Valdesolo, 2018).

The Role of Emotion

Like Piaget, Kohlberg avoided studying emotion, understanding that it can undermine moral reasoning, which was his main focus. However, increasing evidence indicates that emotions play an important role in moral thinking (Spinrad & Eisenberg, 2020). Later in the chapter, we will further explore the importance of emotion in moral development.

Gender and the Care Perspective

The most publicized criticism of Kohlberg's theory has come from Carol Gilligan (1982, 1992, 1996), who argues that Kohlberg's theory reflects a gender bias. According to Gilligan, Kohlberg's theory is based on a male norm that puts abstract principles above relationships and concern for others and sees the individual as standing alone and independently making moral decisions. It puts justice at the heart of morality. In contrast with Kohlberg's **justice perspective,** the **care perspective** is a moral perspective that views people in terms of their connectedness with others and emphasizes interpersonal communication, relationships with others, and concern for others. According to Gilligan, Kohlberg greatly underplayed the care perspective, perhaps because he was a male, because most of his research was with males rather than females, and because he used male responses as the primary source for his theory.

In extensive interviews with girls from 6 to 18 years of age, Gilligan and her colleagues found that girls display greater sensitivity to human relationships based on watching and

Janet Shibley Hyde concluded that many views and studies of gender exaggerate differences. Connect to "Gender and Sexuality."

justice perspective A moral perspective that focuses on the rights of the individual; individuals independently make moral decisions.

care perspective The moral perspective of Carol Gilligan; views people in terms of their connectedness with others and emphasizes interpersonal communication, relationships with others, and concern for others.

listening to other people (Gilligan, 1992; Gilligan & others, 2003). However, a meta-analysis (a statistical analysis that combines the results of many different studies) casts doubt on Gilligan's claim of substantial gender differences in moral judgment (Jaffee & Hyde, 2000). And another analysis concluded that girls' moral orientations are "somewhat more likely to focus on care for others than on abstract principles of justice, but they can use both moral orientations when needed (as can boys . . .)" (Blakemore, Berenbaum, & Liben, 2009, p. 132).

Culture and Moral Reasoning Kohlberg emphasized that his stages of moral reasoning are universal, but some critics claim his theory is culturally biased (Miller, Wice, & Goyal, 2020). Both Kohlberg and his critics may be partially correct. One review of 45 studies in 27 cultures around the world, mostly non-European, provided support for the universality of Kohlberg's first two levels (Snarey, 1987). As Kohlberg predicted, individuals in diverse cultures developed through these first two levels in sequence. Level 3, however, has not been found in all cultures (Gibbs & others, 2007). Furthermore, Kohlberg's scoring system does not recognize the higher-level moral reasoning of certain cultures, ignoring the possibility that moral reasoning might be more culture-specific than Kohlberg envisioned (Snarey, 1987).

One study explored links between culture, mindset, and moral judgment (Narváez & Hill, 2010). In this study, a higher level of multicultural experience was linked to open-mindedness (being cognitively flexible), a growth mindset (perceiving that one's qualities can change and improve through effort), and higher scores on moral judgment.

Darcia Narváez and Tracy Gleason (2013) have described cohort effects regarding moral reasoning. In recent years, postconventional moral reasoning has been declining in college students, not down to the middle level (conventional), but to the lowest level (personal interests) (Thoma & Bebeau, 2008). Narváez and Gleason (2013) also argue that declines in prosocial behavior have occurred in recent years and that humans, especially those living in Western cultures, are "on a fast train to demise." They emphasize that the solution to improving people's moral lives lies in better child-rearing strategies and more effective social supports for families and children. In more recent commentary, Narváez and her colleagues (Christen, Narváez, & Gutzwiller, 2017) stress that economic and technical progress are not linked to moral advances when contemporary societies are compared with earlier sustainable ones that were more in tune with community and planetary well-being.

Let's now take a closer look at the roles of family processes in moral development.

Families and Moral Development Kohlberg argued that family processes are essentially unimportant in children's moral development. He placed greater emphasis on children's peer relations.

Did Kohlberg underestimate the contribution of family relationships to moral development? Most developmentalists emphasize that parents play more important roles in children's moral development than Kohlberg envisioned (Padilla-Walker & Memmott-Elison, 2020). They stress that parents' responsiveness, communication, disciplinary techniques, and many other aspects of parent-child relationships influence children's moral development (Lansford, 2020; Thompson, 2020). We will have more to say about this topic later in the chapter. Nonetheless, most developmentalists agree with Kohlberg and Piaget that peers play an important role in moral development.

In sum, Kohlberg's theory was initially an important pioneering effort in describing and understanding the development of moral reasoning. As indicated in the criticisms of his theory, the theory is no longer nearly as influential as it once was. Let's now explore some additional aspects of moral development.

MORAL BEHAVIOR

What are the basic processes responsible for moral behavior? What is the nature of self-control and resistance to temptation? How do social cognitive theorists view moral development?

Basic Processes The processes of reinforcement, punishment, and imitation have been invoked to explain how individuals learn certain responses and why their responses differ from one another's (Grusec, 2006). When individuals are reinforced for behavior that is consistent with laws and social conventions, they are likely to repeat that behavior. Also, when individuals are punished for immoral behaviors, those behaviors can be eliminated, but at the expense of sanctioning punishment by its very use and of causing emotional side effects for the

individual. And when provided with models who behave morally, individuals are likely to adopt their actions. In one study, 2-year-olds watched a video of an adult engaging in prosocial behavior in response to another person's distress (Williamson, Donohue, & Tully, 2013). Children who saw the prosocial video were more likely than children who did not see it to imitate the prosocial behavior in response to their own parents' distress.

The above comments about reinforcement, punishment, and imitation come with some important qualifiers. The effectiveness of rewards and punishments depends on the consistency and timing with which they are administered. The effectiveness of modeling depends on the characteristics of the model and the cognitive skills of the observer.

Behavior is situationally dependent. Thus, individuals do not consistently display moral behavior in different situations. How consistent is moral behavior? In a classic investigation of moral behavior, one of the most extensive ever conducted, Hugh Hartshorne and Mark May (1928–1930) observed the moral responses of 11,000 children who were given the opportunity to lie, cheat, and steal in a variety of circumstances—at home, at school, at social events, and in athletics. A completely honest or a completely dishonest child was difficult to find. Situation-specific behavior was the rule. Children were more likely to cheat when their friends put pressure on them to do so and when the chance of being caught was slim. However, other analyses suggest that although moral behavior is influenced by situational determinants, some children are more likely than others to cheat, lie, and steal (Burton, 1984).

Resistance to Temptation and Self-Control When pressures mount for individuals to cheat, lie, or steal, it is important to ask whether they have developed the ability to resist temptation and to exercise self-control (Fan & others, 2020; Pino-Pasternak, Valcan, & Malpique, 2019). Walter Mischel (1974) argues that self-control is strongly influenced by cognitive factors. Researchers have shown that children can instruct themselves to be more patient and, in the process, show more self-control.

Social Cognitive Theory The role of cognitive factors in resisting temptation and exercising self-control illustrates ways in which cognitions mediate the link between environmental experiences and moral behavior (Grusec, 2006, 2020; Lapsley, Laporte, & Kelley, 2022). The relationships between these three elements—environment, cognition, and behavior—are highlighted by social cognitive theorists. The **social cognitive theory of morality** emphasizes a distinction between an individual's moral competence (ability to perform moral behaviors) and moral performance (performing those behaviors in specific situations) (Mischel & Mischel, 1975). *Moral competencies* include what individuals are capable of doing, what they know, their skills, their awareness of moral rules and regulations, and their cognitive ability to construct behaviors. Moral competence is the outgrowth of cognitive-sensory processes. *Moral performance,* or behavior, however, is determined by motivation and the rewards and incentives to act in a specific moral way.

developmental **connection**
Social Cognitive Theory
What are the main themes of Bandura's social cognitive theory? Connect to "Introduction."

Albert Bandura (2002, 2015) also stresses that moral development is best understood by considering a combination of social and cognitive factors, especially those involving self-control. He proposed that in developing a moral self, individuals adopt standards of right and wrong that serve as guides and deterrents for conduct. In this self-regulatory process, people monitor their conduct and the conditions under which it occurs, judge it in relation to moral standards, and regulate their actions by the consequences they apply to themselves. They do things that provide them with satisfaction and a sense of self-worth. They refrain from behaving in ways that violate their moral standards because such conduct will bring self-condemnation. Self-sanctions keep conduct in line with internal standards. Thus, in Bandura's view, self-regulation rather than abstract reasoning is the key to positive moral development.

In his most recent book, *Moral Disengagement,* Bandura (2015) described various ways that individuals morally disengage themselves from reprehensible actions and still feel good about themselves. He especially highlights how people may use worthwhile ends to justify inhumane means. As an example, Bandura (2015) points to atrocities committed by ISIS in which religious ideology is used to justify inhumane behavior.

social cognitive theory of morality The theory that distinguishes between moral competence—the ability to produce moral behaviors—and moral performance—performing those behaviors in specific situations.

MORAL FEELING

Think about a time when you did something you sensed was wrong. Did it affect you emotionally? Maybe you had a twinge of guilt. And when you gave someone a gift, you might have felt joy. What role do emotions play in moral development, and how do these emotions develop?

Psychoanalytic Theory According to Sigmund Freud, guilt and the desire to avoid feeling guilty are the foundation of moral behavior. In Freud's theory, the *superego* is the moral branch of personality. The superego consists of two main components: the ego ideal and the conscience. The **ego ideal** rewards the child by conveying a sense of pride and personal value when the child acts according to ideal standards approved by the parents. The **conscience** punishes the child for behaviors disapproved by the parents, making the child feel guilty and worthless.

How does the superego and hence guilt develop? According to Freud, children fear losing their parents' love and being punished for their unacceptable sexual attraction toward the opposite-sex parent. To reduce anxiety, avoid punishment, and maintain parental affection, children identify with the same-sex parent. Through this identification, children *internalize* the parent's standards of right and wrong, which reflect societal prohibitions, and hence develop their superego. Also, the child turns inward the hostility that was previously aimed externally at the same-sex parent. This inwardly directed hostility is then experienced self-punitively (and unconsciously) as guilt. In the psychoanalytic account of moral development, children conform to societal standards to avoid guilt. In this way, self-control replaces parental control.

Freud's claims regarding the formation of the ego ideal and conscience cannot be verified. However, researchers can examine the extent to which children feel guilty when they misbehave. Contemporary views of conscience emphasize that conscience is rooted in close relationships, constructed from advances in children's understanding of self and others, and linked to their emotions (Thompson, 2020).

Contemporary views also stress that the development of conscience goes well beyond disciplinary encounters with parents to include guilt as a motivator for cooperation and the moral influence of positive relationships between parents and children.

Recent research focuses on the role of guilt in young children's cooperation. For example, researchers have found that experiencing guilt motivates reparative behavior as early as 2 to 3 years of age and that transgressors' displays of guilt motivate cooperative behavior in 4- to 5-year-olds (Vaish, 2018; Vaish, Carpenter, & Tomasello, 2016).

A major interest regarding young children's conscience focuses on children's relationships with their caregivers. Especially important in this regard is the emergence of young children's willingness to embrace the values of their parents, an orientation that flows from a positive, close relationship (Kochanska & Aksan, 2007). For example, children who are securely attached are more likely to internalize their parents' values and rules (Kim & Kochanska, 2017). Also, a recent study revealed that mothers' engagement in mind-mindedness (being tuned in to their infant's emotions, desires, and interests) when talking to infants was linked to their children's higher level of conscience at 6 years of age (Goffin, Kochanska, & Yoon, 2020). And in another recent study, lower maternal sensitivity in early childhood was associated with a less effective conscience in early childhood and increased conduct problems in the elementary school years (Ettekal & others, 2020).

What characterizes a child's conscience?
Markus Mainka/Shutterstock

Empathy Positive feelings, such as empathy, contribute to the child's moral development (Spinrad & Eisenberg, 2020). **Empathy** is an affective response to another's feelings with an emotional response that is similar to the other person's feelings. To empathize is not just to sympathize; it is to put oneself in another's place emotionally.

Although empathy is an emotional state, it has a cognitive component—the ability to discern another's inner psychological states, or what we have previously discussed as *perspective taking* (Eisenberg, Spinrad, & Valiente, 2016; Spinrad & Eisenberg, 2020). Infants have the capacity for some purely empathic responses, but for effective moral action, children must learn to identify a wide range of emotional states in others and to anticipate what kinds of actions will improve another person's emotional state.

What are the milestones in children's development of empathy? According to an analysis by child developmentalist William Damon (1988), changes in empathy take place in early infancy, at 1 to 2 years of age, in early childhood, and at 10 to 12 years of age.

Global empathy is the young infant's empathic response in which clear boundaries between the feelings and needs of the self and those of another have not yet been established. For example, one 11-month-old infant fought off her own tears, sucked her thumb, and buried her head in her mother's lap after she had seen another child fall and hurt himself. Not all infants cry every time someone else is hurt, though. Many times, an infant will stare at another's pain with curiosity. Although global empathy is observed in some infants, it does not consistently characterize all infants' behavior.

ego ideal The component of the superego that rewards the child by conveying a sense of pride and personal value when the child acts according to ideal standards approved by the parents.

conscience The component of the superego that punishes the child for behaviors disapproved of by parents by making the child feel guilty and worthless.

empathy Reacting to another's feelings with an emotional response that is similar to the other's feelings.

FIGURE 1

DAMON'S DESCRIPTION OF DEVELOPMENTAL CHANGES IN EMPATHY.

Age Period	Nature of Empathy
Early infancy	Characterized by global empathy, the young infant's empathic response does not distinguish between feelings and needs of self and others.
1 to 2 years of age	Undifferentiated feelings of discomfort at another's distress grow into more genuine feelings of concern, but infants cannot translate realization of others' unhappy feelings into effective action.
Early childhood	Children become aware that every person's perspective is unique and that someone else may have a different reaction to a situation. This awareness allows the child to respond more appropriately to another person's distress.
10 to 12 years of age	Children develop an emergent orientation of empathy for people who live in unfortunate circumstances—the poor, the handicapped, and the socially outcast. In adolescence, this newfound sensitivity may give a humanitarian flavor to the individual's ideological and political views.

What characterizes children's empathy and sympathy?
StockPlanets/Getty Images

When they are 1 to 2 years of age, infants may feel genuine concern for the distress of other people, but only when they reach early childhood can they respond appropriately to another person's distress. This ability depends on children's new awareness that people have different reactions to situations. By late childhood, they may begin to feel empathy for the unfortunate. To read further about Damon's description of the developmental changes in empathy from infancy through adolescence, see Figure 1.

In one study, researchers found that empathy increased from 12 to 16 years of age (Allemand, Steiger, & Fend, 2015). Also in this study, girls showed more empathy than boys did. Further, adolescent empathy predicted a number of social competencies (adult empathy, communication skills, and relationship satisfaction, for example) two decades later. In addition, a recent study revealed that a higher degree of empathy was linked to greater civic engagement by adolescents (Metzger & others, 2018). Also, in a recent meta-analysis, it was concluded that better-quality parent-child and peer relationships were linked to higher levels of empathy during adolescence (Boele & others, 2019).

The Contemporary Perspective on the Role of Emotion in Moral Development We have seen that classical psychoanalytic theory emphasizes the power of unconscious guilt in moral development but that other theorists, such as Damon, emphasize the role of empathy. Today, many child developmentalists believe that both positive feelings—such as empathy, sympathy, admiration, and self-esteem—and negative feelings—such as anger, outrage, shame, and guilt—contribute to children's moral development (Spinrad & Eisenberg, 2020).

Emotions provide a natural base for children's acquisition of moral values, motivating them to pay close attention to moral events (Grusec & Davidov, 2019; Malti, Peplak, & Acland, 2020). However, moral emotions do not operate in a vacuum to build a child's moral awareness, and they are not sufficient in themselves to generate moral responses. They do not give the "substance" of moral regulation—the rules, values, and standards of behavior that children need to understand and act on. Moral emotions are inextricably interwoven with the cognitive and social aspects of children's development (Spinrad & Eisenberg, 2020).

MORAL PERSONALITY

So far we have examined three key dimensions of moral development: thoughts, behavior, and feelings. Recently, there has been a surge of interest in a fourth dimension: personality (Lapsley, LaPorte, & Kelley, 2022; Strohminger, 2018; Walker, 2016). Thoughts, behavior, and feelings can all be involved in an individual's moral personality. For many years, skepticism surrounded the idea that a set of moral characteristics or traits could be discovered that would constitute a core of moral personality. Much of this skepticism stemmed from the results of Hartshorne and May's (1928–1930) classic study as well as Walter Mischel's (1968) social learning theory and research, which argued that situations trump traits when attempts are made to predict moral behavior. Mischel's (2004) subsequent research and theory and Bandura's (2012) social cognitive theory have emphasized the importance of "person" factors while still

recognizing situational variation. Until recently, though, there has been little interest in studying what might constitute a moral personality. Three aspects of moral personality that have recently been emphasized are (1) moral identity, (2) moral character, and (3) moral exemplars.

Moral Identity A central aspect of the recent interest in the role of personality in moral development focuses on **moral identity.** Individuals have a moral identity when moral notions and commitments are central to their life (Hardy, Krettenauer, & Hunt, 2020). In this view, behaving in a manner that violates this moral commitment places the integrity of the self at risk (Lapsley, LaPorte, & Kelley, 2022; Lapsley, Reilly, & Narváez, 2020). To evaluate the extent to which you have a moral identity, see Figure 2.

Darcia Narváez (2010) concluded that a mature moral individual cares about morality and being a moral person. For these individuals, moral responsibility is central to their identity. Mature moral individuals engage in moral metacognition, including moral self-monitoring and moral self-reflection. Moral self-monitoring involves monitoring one's thoughts and actions related to moral situations, and engaging in self-control when it is needed. Moral self-reflection encompasses critical evaluations of one's self-judgments and efforts to minimize bias and self-deception.

Might moral identity change from adolescence through the adult years? In a recent study of individuals from adolescence through middle adulthood, external moral identity motivation (reflected in one's self-interest and reputation) decreased while internal moral identity motivation (characterized by concern about consequences for others, being a role model, adherence to one's self-ideals, and what an ideal relationship is) increased, suggesting that as people get older, moral motivation becomes more self-other integrated in a positive direction (Krettenauer & Victor, 2017).

What are some outcomes of having a moral identity? A study of 9,500 college students revealed that moral identity predicted all five health outcomes assessed (anxiety, depression, hazardous alcohol use, sexual risk taking, and self-esteem) (Hardy & others, 2013).

Earlier in this chapter, we discussed Albert Bandura's (2015) recent ideas about moral disengagement and how too many people disengage themselves from morally reprehensible actions and still manage to feel morally good about themselves. While an individual's commitment to a moral identity emphasizes the importance of behaving in a moral way, engaging in moral disengagement shields an individual from thinking that he or she has done something

Do You Have a Moral Identity?

A moral identity questionnaire has been developed that provides a list of moral traits and asks individuals to determine the extent to which these traits characterize a person they know (Aquino & Reed, 2002). The person with these characteristics could be you or it could be someone else. For a moment, visualize the kind of person who has these characteristics. Imagine how the individual would think, feel, and act. When you have a clear image of what this person would be like, answer the questions that follow.

Moral Traits

Caring
Compassionate
Fair
Generous
Helpful
Honest
Kind

Questions

- Is being someone who has these characteristics an important part of who you are?
- Are you involved in activities that indicate to others that you have these characteristics?
- Would it make you feel good to have these characteristics?

FIGURE **2**

DO YOU HAVE A MORAL IDENTITY?

Source: After Aquino, R., & Reed, A. (2002), The self-importance of moral identity. *Journal of Personality and Social Psychology, 83,* 1427–1428.

Rosa Parks (*top photo*, sitting in the front of a bus after the U.S. Supreme Court ruled that segregation was illegal on her city's bus system) and Andrei Sakharov (bottom photo) are moral exemplars. Parks (1913–2005), an African American seamstress in Montgomery, Alabama, became famous for her quiet, revolutionary act of not giving up her bus seat to a non-Latinx White man in 1955. Her heroic act is cited by many historians as the beginning of the modern civil rights movement in the United States. Across the next four decades, Parks continued to work for progress in civil rights. Sakharov (1921–1989) was a Soviet physicist who spent several decades designing nuclear weapons for the Soviet Union and came to be known as the father of the Soviet hydrogen bomb. However, later in his life he became one of the Soviet Union's most outspoken critics and worked relentlessly to promote human rights and democracy.

What role does moral disengagement play in bullying?
Brycia James/Getty Images

immoral or wrong (Lapsley, LaPorte, & Kelley, 2022). Recent research on bullying has found that bullies especially use moral disengagement strategies (Travlos & others, 2021). A meta-analysis confirmed that moral disengagement is a significant factor in the aggressive behavior of bullies (Gini, Pozzoli, & Hymel, 2014). Also, a recent three-year longitudinal study of young adolescents revealed that over time adolescents who increased their verbal bullying had a higher level of moral disengagement (Bjarehed & others, 2021). And recent research indicates that having low empathy is likely linked to a bully's moral disengagement and aggressive behavior (Mascia & others, 2021).

Moral Character James Rest (1995) argued that moral character has not been adequately emphasized in moral development. In Rest's view, *moral character* involves having strong convictions, persisting, and overcoming distractions and obstacles. If individuals don't have moral character, they may wilt under pressure or fatigue, fail to follow through or become distracted and discouraged, and fail to behave morally. Of course, such persistence or *grit* is necessary to complete any difficult task, regardless of whether the person has moral aims in mind. Moral character presupposes that the person has set moral goals and that achieving those goals involves the commitment to act in accord with those goals (Helzer & Critcher, 2018). Rest (1995) also concluded that motivation has not been adequately emphasized in moral development. In Rest's view, *moral motivation* involves prioritizing moral values over other personal values.

Lawrence Walker (2002) has studied moral character by examining people's conceptions of moral excellence. Among the moral virtues people emphasize are "honesty, truthfulness, and trustworthiness, as well as those of care, compassion, thoughtfulness, and considerateness. Other salient traits revolve around virtues of dependability, loyalty, and conscientiousness" (Walker, 2002, p. 74). In Walker's perspective, these aspects of moral character provide a foundation for positive social relationships and optimal functioning.

Moral Exemplars **Moral exemplars** are people who have lived exemplary lives. Moral exemplars have a moral personality, identity, character, and a set of virtues that reflect moral excellence and commitment (Walker, 2014, 2016). The point of studying and conducting research on moral exemplars is to be able to characterize the ideal endpoint of moral development and understand how people got there.

One study examined the personalities of exemplary young adults to determine what characterized their moral excellence (Matsuba & Walker, 2004). Forty young adults were nominated by executive directors of a variety of social organizations (such as Big Brothers, AIDS Society, and Ronald McDonald House) as moral exemplars based on their extraordinary moral commitment to these social organizations. They were compared with 40 young adults matched in age, education, and other variables who were attending a university. The moral exemplars were more advanced in moral reasoning, further along in developing an identity, and more likely to be in close relationships.

SOCIAL DOMAIN THEORY

moral exemplars People who have a moral personality, identity, character, and set of virtues that reflect moral excellence and commitment.

social domain theory Theory that identifies different domains of social knowledge and reasoning, including moral, social conventional, and personal domains. These domains arise from children's and adolescents' attempts to understand and deal with different forms of social experience.

social conventional reasoning Focuses on conventional rules established by social consensus and convention, as opposed to moral reasoning, which stresses ethical issues.

Social domain theory states that there are different domains of social knowledge and reasoning, including moral, social conventional, and personal domains. In social domain theory, children's and adolescents' moral, social conventional, and personal knowledge and reasoning emerge from their attempts to understand and deal with different forms of social experience (Jambon & Smetana, 2020). In the view of leading experts Judith Smetana (2013) and Eliot Turiel (2018), social domain theory emphasizes that the key aspects of morality involve judgments about welfare, justice, and rights as well as struggles that individuals face in regard to moral issues in their social lives. Social domain theory stresses that children, even very young ones, are motivated to evaluate and make sense of their social world (Jambon & Smetana, 2020).

Social conventional reasoning focuses on conventional rules that have been established by social consensus in order to control behavior and maintain the social system (Jambon & Smetana, 2020). The rules themselves are arbitrary, such as raising your hand in class before speaking, using one staircase at school to go up and the other to go down, not cutting in front of someone standing in line to buy movie tickets, and stopping at a stop sign when driving. There are sanctions if we violate these conventions, although the rules can be changed by

consensus. In contrast, moral reasoning focuses on ethical issues and rules of morality. Unlike conventional rules, moral rules are not arbitrary. They are obligatory, widely accepted, and somewhat impersonal (Turiel, 2018). Rules pertaining to lying, cheating, stealing, and physically harming another person are moral rules because violation of these rules affronts ethical standards that exist apart from social consensus and convention. Moral judgments involve concepts of justice, whereas social conventional judgments are concepts of social organization. Violating moral rules is usually more serious than violating conventional rules.

The social conventional approach is a serious challenge to Kohlberg's approach because Kohlberg argued that social conventions are mixed in with moral concerns at the conventional level, a developmental stop-over on the road to higher moral sophistication, postconventional reasoning, where they are separated. For proponents of social conventional reasoning, social conventional reasoning is not lower than postconventional reasoning but rather something that needs to be disentangled from the moral thread (Jambon & Smetana, 2020). However, in a recent study, children and adolescents said that changes in moral beliefs are more disruptive to one's identity than changes in social-conventional beliefs are (Lefebvre & Krettenaur, 2020). Also in this study, children and adolescents reported that changes in negative moral beliefs are more disruptive to one's identity than changes in positive moral beliefs are.

Recently, a distinction also has been made between moral and conventional issues, which are viewed as legitimately subject to adult social regulation, and personal issues, which are more likely subject to the child's or adolescent's independent decision making and personal discretion (Jambon & Smetana, 2020). Personal issues include control over one's body, privacy, and choice of friends and activities. Thus, some actions belong to a *personal* domain not governed by moral strictures or social norms.

How does social conventional reasoning differ from moral reasoning? What are some examples of social conventional reasoning?

2 Contexts of Moral Development

LG2 Explain how parents, schools, and culture influence moral development.

Parenting | Schools | Culture

So far, we have examined the four principal domains of moral development—thoughts, behaviors, feelings, and personality. We saw that both Piaget and Kohlberg noted that peer relations exert an important influence on moral development. What other contexts play a role in moral development? In particular, what are the roles of parents,schools, and culture?

What are some aspects of relationships between parents and children that contribute to children's moral development?
Fuse/Getty Images

PARENTING

Both Piaget and Kohlberg held that parents do not provide unique or essential inputs to children's moral development. Parents, in their view, are responsible for providing role-taking opportunities and cognitive conflict, but peers play the primary role in moral development. Research reveals that siblings and peers, as well as parents, contribute to children's moral maturation (Lapsley, 2020; Mounts & Allen, 2020; Thompson, 2020).

In Ross Thompson's (2009, 2020) view, young children are moral apprentices, striving to understand what is moral. They can be assisted in this quest by the "sensitive guidance of adult mentors in the home who provide lessons about morality in everyday experiences" (Thompson, 2009). Among the most important aspects of the parent-child relationship that contribute to children's moral development are relational quality, proactive strategies, and conversational dialogue.

Relational Quality Parent-child relationships introduce children to the mutual obligations of close relationships that involve warmth and responsibility (Laible & others, 2020; Thompson, 2020). Parents' obligations include engaging in positive caregiving and guiding children to become competent human beings. Children's obligations include responding appropriately to parents' initiatives and maintaining a positive relationship with parents.

In terms of relationship quality, secure attachment may play an important role in children's moral development (Thompson, 2020). A secure attachment can place the child on a positive path for internalizing parents' socializing goals and family values. In one study, secure attachment in infancy was linked to earlier development of conscience (Laible & Thompson, 2000). In another study, early secure attachment defused a maladaptive trajectory toward antisocial outcomes (Kochanska & others, 2010).

developmental **connection**
Attachment
Securely attached infants use the caregiver as a secure base from which to explore the environment. Connect to "Emotional Development and Attachment."

Proactive Strategies An important parenting strategy is to proactively avert potential misbehavior by children before it takes place (Padilla-Walker & Son, 2020; Thompson, 2020). With younger children, being proactive means using diversion, such as distracting their attention or moving them to alternative activities. With older children, being proactive may involve talking with them about values that the parents deem important. Transmitting these values can help older children and adolescents resist temptations that inevitably emerge in contexts outside the scope of direct parental monitoring, such as peer relations and the media.

Both theory and empirical data support the conclusion that parents play an important role in children's moral development.

—Nancy Eisenberg
Contemporary Psychologist, Arizona State University

Conversational Dialogue Conversations related to moral development can benefit children, whether they occur as part of a discipline encounter or during the everyday stream of parent-child interaction (Spinrad & Eisenberg, 2020; Thompson, 2020). The conversations can be planned or spontaneous and can focus on topics such as past events (for example, a child's prior misbehavior or positive moral conduct), shared future events (for example, going somewhere that may involve a temptation and will require positive moral behavior), and immediate events (for example, talking with the child about a sibling's tantrums). Even when they are not intended to teach a moral lesson or explicitly encourage better moral judgment, such conversations can contribute to children's moral development.

Parenting Recommendations Nancy Eisenberg and her colleagues (Eisenberg & Spinrad, 2016; Spinrad & Eisenberg, 2020) suggest that parents who adopt the following strategies are more likely to have children who behave morally:

- Are warm and supportive, use inductive reasoning, and engage in authoritative parenting
- Are not punitive and do not use love withdrawal as a disciplinary strategy
- Provide opportunities for children to learn about others' perspectives and feelings
- Involve children in family decision making and in the process of thinking about moral decisions
- Model moral behaviors and thinking themselves, and provide opportunities for their children to do so

- Provide information about what behaviors are expected and why
- Foster an internal rather than an external sense of morality
- Help children to understand and regulate negative emotion rather than becoming overaroused

Parents who show this configuration of behaviors likely foster in their children concern and caring about others and create a positive parent-child relationship. One study found that adolescents' moral motivation was positively linked to the quality of their relationship with their parents (Malti & Buchmann, 2010). Also, in a recent study of fifth-, tenth-, and twelfth-grade students, authoritative parents (showing a combination of warmth and control) were more likely to have children and youth who showed higher levels of prosocial behavior than parents who were moderately demanding and uninvolved (Carlo & others, 2018).

SCHOOLS

No matter how parents treat their children at home, they may feel that they have little control over a great deal of their children's moral education. Children spend extensive time away from their parents at school, and the time spent can influence children's moral development (Lapsley, Reilly, & Narváez, 2020).

The Hidden Curriculum

More than 80 years ago, educator John Dewey (1933) recognized that even when schools do not have specific programs in moral education, they provide moral education through a "hidden curriculum." The **hidden curriculum** refers to the way certain behaviors are expected and rewarded (such as waiting in turn and obeying teacher directives without question) and others are suppressed or punished (such as speaking out of turn and joking). The hidden curriculum forms part of the moral atmosphere that is present in every school. The moral atmosphere is created by school and classroom rules, the moral orientation of teachers and school administrators, and text materials. Teachers serve as models of ethical or unethical behavior (Sanger, 2008). Classroom rules and peer relations at school transmit attitudes about cheating, lying, stealing, and consideration for others. And through its rules and regulations, the school administration infuses the school with a value system.

Recently, increased attention has been directed to the influence of classroom and school climate as part of the hidden curriculum. Darcia Narváez (2010) argues that attention should be given to the concept of "sustaining climates." In her view, a sustaining classroom climate is more than a positive learning environment and more than a caring context. Sustaining climates involve focusing on students' sense of purpose, social engagement, community connections, and ethics. In sustaining classroom and school climates, students learn skills for flourishing and reaching their potential and help others to do so as well.

Character Education

In 2018, 18 states had a legislative mandate for **character education** in schools, another 18 had legislation that encouraged character education, 7 supported character education but without legislation, and 8 had no legislation specifying character education. The classic character education approach is to model good behavior and directly teach virtue, instructing students that behaviors such as lying, stealing, and cheating are wrong, whereas honesty and obedience are right (Ruch & Wagner, 2020). Teachers of traditional character education programs model and directly teach moral behavior to their students (Lapsley, Reilly, & Narváez, 2020).

As part of a traditional approach, every school should have an explicit moral code that is clearly communicated to students. According to traditional views of character education, any violations of the code should be met with sanctions. Newer approaches advocate a more democratic solution. Instruction in specified moral concepts, such as cheating, can take the form of example and definition, class discussions and role playing, or rewards for students exhibiting proper behavior. Alternatives to the traditional approach have been on the increase. For example, assisting students to develop a care perspective that involves considering others' feelings and helping others has been accepted as a relevant aspect of character education (Noddings, 2014). And recently it has been noted that purpose likely is an important aspect of character that should be emphasized in character education. In a recent study, three components of character (gratitude, compassion, and grit) were linked to character in young adolescents (Malin, Liauw, & Damon, 2017).

hidden curriculum The pervasive moral atmosphere that characterizes every school.

character education A direct moral education program in which students are taught moral literacy to prevent them from engaging in immoral behavior.

Jewel Cash, seated next to her mother, participates in a crime-watch meeting at a community center. Exemplifying teenage community involvement, Jewel swayed a neighborhood group to support her proposal for a winter jobs program. Raised in one of Boston's housing projects by her mother, a single parent, Cash served on the Boston Student Advisory Council, mentored children, volunteered at a women's shelter, and belonged to a neighborhood crime-watch organization (Silva, 2005).
Matthew J. Lee/The Boston Globe/Getty Images

Lawrence Walker (2002) argues that it is important for character education to involve more than a listing of moral virtues on a classroom wall. Instead, he emphasizes that children and adolescents need to participate in critical discussions of values; they need to discuss and reflect on how to incorporate virtues into their daily lives. Walker also advocates exposing children to moral exemplars worthy of emulating and getting them to participate in community service. The character education approach reflects the moral personality domain of moral development discussed earlier in the chapter.

Service Learning

Service learning is a form of education that promotes social responsibility and service to the community. In service learning, adolescents engage in activities such as tutoring, helping older adults, working in a hospital, assisting at a child-care center, or cleaning up a vacant lot to make a play area. An important goal of service learning is for adolescents to become less self-centered and more strongly motivated to help others (Pancer, 2020). Service learning is often more effective when two conditions are met (Nucci, 2006): (1) students are given some degree of choice in the service activities in which they participate, and (2) students are provided opportunities to reflect on their participation.

Service learning takes education out into the community (Hart, 2020). Adolescent volunteers tend to be extraverted, committed to others, and have a high level of self-understanding (Eisenberg & Morris, 2004). One study revealed that adolescent girls participated more in service learning than adolescent boys did (Webster & Worrell, 2008).

Researchers have found that service learning benefits adolescents and emerging adults in a number of ways (Hart, 2020). These improvements include higher grades in school, increased goal setting, higher self-esteem, an enhanced sense of empowerment to make a difference for others, and an increased likelihood of serving as volunteers in the future. In one study, 74 percent of African American and 70 percent of Latinx adolescents said that service-learning programs could have a "fairly or very big effect" on keeping students from dropping out of school (Bridgeland, Dilulio, & Wulsin, 2008).

service learning A form of education that promotes social responsibility and service to the community.

An analysis revealed that 26 percent of U.S. public high schools require students to participate in service learning (Metz & Youniss, 2005). The benefits of service learning, for both the volunteer and the recipient, suggest that more adolescents should be required to participate in such programs (Enfield & Collins, 2008).

Cheating

A common moral education concern is whether students cheat and how adults should handle the cheating when it is discovered (Steger, Schroeders, & Wilhelm, 2021). Academic cheating can take many forms, including plagiarism, using "cheat sheets" during an exam, copying from a neighbor during a test, purchasing papers, and falsifying lab results. A 2012 survey revealed that 51 percent of secondary school students said they had cheated on a test in school during the past year (Josephson Institute of Ethics, 2012). Also, a recent survey of college students indicated that 86 percent said they have cheated (Kessler International, 2017). In this survey, students reported that the advent of online classes and sophisticated mobile devices make it easier than ever to cheat.

Why do students cheat? What are some strategies teachers can adopt to prevent cheating?
Eric Audras/PhotoAlto/Getty Images

Why do students cheat? Among the reasons students give for cheating are pressure to get high grades, time constraints, poor teaching, and lack of interest (Stephens, 2008). In terms of poor teaching, "students are more likely to cheat when they perceive their teacher to be incompetent, unfair, and uncaring" (Stephens, 2008, p. 140).

A long history of research also implicates the power of the situation in determining whether students cheat (Hartshorne & May, 1928–1930). For example, students are more likely to cheat when they are not being closely monitored during a test; when they know their peers are cheating; when they know that another

student has cheated without being caught; and when student scores are made public (Carrell, Malmstrom, & West, 2008).

Certain personality traits also are linked to cheating. One study revealed that college students who engaged in academic cheating were characterized by the personality traits of low conscientiousness and low agreeableness (Williams, Nathanson, & Paulhus, 2010).

Among the strategies for decreasing academic cheating are preventive measures such as making sure students are aware of what constitutes cheating, explaining the consequences if they do cheat, closely monitoring students' behavior while they are taking tests, and emphasizing the importance of being a moral, responsible individual who practices academic integrity. In promoting academic integrity, many colleges have instituted an honor code that emphasizes self-responsibility, fairness, trust, and scholarship. However, few secondary schools have developed honor code policies. The International Center for Academic Integrity (www.academicintegrity.org/icai/home.php) has extensive materials available to help schools develop academic integrity policies.

Integrative Approaches Darcia Narváez (2010, 2020) emphasizes an *integrative approach* to moral education that encompasses both the reflective moral thinking and commitment to justice advocated in Kohlberg's approach, and developing virtues as advocated in the character education approach. She highlights the Child Development Project as an excellent example of integrative moral education. In the Child Development Project, students are given multiple opportunities to discuss other students' experiences, which inspires empathy and perspective taking, and they participate in exercises that encourage them to reflect on their own behaviors in terms of values such as fairness and social responsibility (Battistich, 2008; Solomon, Watson, & Battistich, 2002). Adults coach students in ethical decision making and guide them in becoming more caring individuals. Students experience a caring community, not only in the classroom but also in after-school activities and through parental involvement in the program. Research evaluations of the Child Development Project indicate that it is related to an improved sense of community, increased prosocial behavior, better interpersonal understanding, and greater use of social problem solving (Battistich, 2008; Solomon & others, 1990).

CULTURE

Earlier in the chapter, we described how culture plays a much stronger role in moral development than Kohlberg envisioned. Here we expand this discussion, focusing on cultural similarities and variations in moral development.

Some aspects of morality, such as honesty, are endorsed across most cultures. However, other aspects of morality have shown variations in different cultures (Graham, 2020; Jensen, 2020a, b). Researchers have found that people in Western, Educated, Industrialized, Rich, and Democratic (WEIRD) cultures are more likely to have moral codes that are characterized by individual rights and independence, while those in non-WEIRD cultures are more likely to endorse duty-based communal obligations and a collective, interdependence (Graham & others, 2016). Further, cultural variations in shame, guilt, and pride have been found. In one study, children in Japan showed the highest level of shame, children in Korea the highest level of guilt, and children in the United States the highest level of pride (Furukawa, Tangney, & Higashibara, 2012).

Differences also can occur within a particular society. For example, in the United States, individuals of higher socioeconomic status (SES) make more utilitarian decisions when faced with moral dilemmas than their lower-SES counterparts (Cote, Piff, & Willer, 2013). A further within-culture moral variation is that lower-SES individuals in WEIRD cultures tend to be more cooperative than higher-SES individuals (Piff & others, 2010). Lower-SES individuals also have been found to be less likely to lie or cheat, at least in part because wealthier individuals are more likely to accept greed (Piff & others, 2012).

In addition, recent research has increasingly examined how families socialize children's moral development (Carlo & Pierotti, 2020). For example, *familism* values stress the importance of giving priority to obligations and maintaining close family relationships. Research indicates that familism is especially important in Mexican American and Latinx families. In one study, young adolescents in Mexican American families who strongly endorsed familism values had higher scores on measures of prosocial tendencies (Knight & others, 2014). In the next main section of the chapter, in our further coverage of prosocial behavior, we will describe other research on Latinx families.

How might Mexican American families contribute to their children's and adolescents' moral development?

3 Prosocial and Antisocial Behavior

LG3 Describe the development of prosocial and antisocial behavior.

Prosocial Behavior

Antisocial Behavior

Service learning encourages positive moral behavior. This behavior is not just moral behavior but behavior that is intended to benefit other people, and psychologists call it prosocial behavior (Carlo & Conejo, 2020; Carlo & Pierotti, 2020). Of course, people have always engaged in antisocial behavior as well. In this section, we take a closer look at prosocial and antisocial behavior, focusing on how they develop.

PROSOCIAL BEHAVIOR

Caring about the welfare and rights of others, feeling concern and empathy for them, and acting in a way that benefits others are all components of prosocial behavior (Spinrad & Eisenberg, 2020). What motivates this behavior, and how does it develop in children?

It is one of the beautiful compensations of this life that no one can sincerely try to help another without helping himself.

—Charles Dudley Warner
American Essayist, 19th Century

Altruism and Reciprocity The purest forms of prosocial behavior are motivated by **altruism,** an unselfish interest and voluntary effort in helping another person. Human acts of altruism are plentiful. Think of the hardworking laborer who places $5 in a Salvation Army kettle, the volunteers at homeless shelters, the person who donates a kidney so someone else can live. Altruism is found throughout the human world. It is also taught by every widely practiced religion in the world—Christianity, Judaism, Islam, Hinduism, Buddhism. The circumstances most likely to evoke altruism are empathy for an individual in need or a close relationship between the benefactor and the recipient (Batson, 1989).

How might the development of altruistic prosocial behaviors vary by ethnicity? Read the *Connecting with Research* interlude to learn about one researcher who applied a traditional model of the development of altruistic prosocial behaviors to Latinx adolescents.

The notion of *reciprocity*, which is the obligation to return a favor with another favor, pervades human interactions all over the world. Some nonprofit organizations try to exploit the norm of reciprocity when they send free calendars or other knickknacks in the mail, hoping that you'll feel obligated to reciprocate with a donation to their cause. People feel guilty when they do not reciprocate, and they may feel angry if someone else does not reciprocate. Reciprocity or altruism may motivate many important prosocial behaviors, including sharing.

altruism An unselfish interest and voluntary effort in helping another person.

Do Infants Have Moral Awareness and Engage in Prosocial Behavior? Recently, researchers have explored whether infants and toddlers have a moral awareness and motivation for prosocial behavior. How can moral awareness and prosocial behavior be studied in preverbal infants? Just as adults do, babies tend to look at something they find interesting or surprising. And when they are given a choice between looking at two things, babies look longer at the more pleasing thing. Based on these assumptions, several studies using the

connecting with research

How Do Parent and Peer Relationships Influence Latinx Adolescents' Prosocial Behavior?

Courtesy Gustavo Carlo

Gustavo Carlo
Key Points:
- prosocial behaviors
- Latinx adolescents
- socialization

Dr. Gustavo Carlo (2021) has spent many years engaged in studies involving Latinx families and youth. In one study, he compared a traditional model of the development of altruistic and public prosocial behaviors, based largely on findings from non-minority adolescents, to Latinx adolescents (Carlo, Streit, & Crockett, 2018). The participants were 15 years old and lived in predominantly non-Latinx White communities.

Applying the traditional model, the strength of parental and peer support was predicted to be linked to altruistic and public prosocial behaviors. The following categories were assessed:

- Parental support, measured with ten items using prompts such as "[the caregiver] believes in showing her/his love for you."
- Peer support, measured with twelve items using prompts such as, "I can count on my friends when I need to get something off my chest."
- Likelihood of engaging in altruistic prosocial behaviors, measured with four items using prompts similar to "When I help someone, there is no need for them to return the favor."
- Likelihood of engaging in public prosocial behaviors, measured with seven items using prompts such as "I can help others best when people are watching me."

The traditional model also led Dr. Carlo to predict that perspective taking, empathic concern, and prosocial moral reasoning would be important in the development of altruistic and public prosocial behaviors. In this regard, Latinx adolescents were asked about these categories:

- Perspective taking, measured with seven items using prompts such as "When I am upset at someone, I usually try to 'put myself in their shoes' for a while."
- Empathic concern, measured with seven items using prompts such as "I often have tender, concerned feelings for people less fortunate than me."

Prosocial moral reasoning was measured by assessing responses to five stories featuring characters whose needs or desires were in conflict with those of others. After reading each story, the adolescents were asked to explain what the characters should do and why.

The results indicated that strong parental support was associated with a higher level of prosocial moral reasoning, which led to Latinx adolescents engaging in more altruistic prosocial behaviors but fewer public prosocial behaviors. Strong peer support resulted in more Latinx adolescents engaging in more altruistic prosocial behaviors and public prosocial behaviors, but only when a path through perspective taking, empathic concern, and prosocial moral reasoning occurred. In sum, the results confirmed that the traditional model can be generalized to the prosocial development of Latinx adolescents.

Based on this model, what role might teachers or guidance counselors play in the development and encouragement of altruistic prosocial behaviors?

violation of expectations technique described in Renee Baillargeon's research (described in the chapter on "Cognitive Developmental Approaches") have found that characters who hinder or harm others are viewed more negatively by infants as young as 4 months of age and that infants will act to punish hinderers and to reward helpers (Hamlin & Sitch, 2021; Van de Vondervoort & Hamlin, 2018). Also, in a recent study of Chinese and Dutch 17- to 26-month-olds, the toddlers displayed more happiness (smiling more, for example) after giving treats to others than they did when receiving treats (Song, Broekhuizen, & Dubas, 2020). At this point, it is wise to interpret these conclusions with caution until they have been confirmed by more research and other measures.

Research indicating that older infants and toddlers use an innate sense of fairness to evaluate observed behavior suggests the presence of an early foundation for moral awareness that is not anticipated in Piaget's and Kohlberg's theories of moral development. However, the view that the emergence of morality in infancy is innate has been described as problematic (Carpendale & Hammond, 2016). Critics of the innate view argue that morality may emerge through infants' early interaction with others and grow with developments in language and reflective thought.

Next, we further explore sharing and fairness, focusing on the childhood and adolescent years.

How does children's sharing change from the preschool to the elementary school years?
Monalyn Gracia/Getty Images

Sharing and Fairness William Damon (1988) described a developmental sequence through which sharing develops in children. Unlike the recent research just described that indicates toddlers can engage in sharing and fairness and have a moral awareness, Damon proposed that sharing during the first three years of life is done for nonempathetic reasons such as the fun of social play or simply for imitation. Then, at about 4 years of age, a combination of newly developed empathetic awareness and adult encouragement produces a sense of obligation on the part of the child to share with others. Most 4-year-olds are not selfless saints, however. Children believe they have an obligation to share but do not necessarily think they should be as generous to others as they are to themselves. Neither do their actions always support their beliefs, especially when they covet an object. What is important developmentally is that the child has developed a belief that sharing is an obligatory part of a social relationship and involves a question of right and wrong. These early ideas about sharing set the stage for giant strides that children make in the years that follow.

By the start of the elementary school years, children begin to express more complicated notions of what is fair. Throughout history, varied definitions of fairness have been used as the basis for distributing goods and resolving conflicts. These definitions involve the principles of equality, merit, and benevolence—*equality* means that everyone is treated the same; *merit* means giving extra rewards for hard work, a talented performance, or other laudatory behavior; *benevolence* means giving special consideration to individuals in a disadvantaged condition.

Equality is the first of these principles used regularly by elementary school children. It is common to hear 6-year-old children use the word *fair* as synonymous with *equal* or *same*. By the mid to late elementary school years, children also believe that equality means special treatment for those who deserve it—a belief that applies the principles of merit and benevolence. In a recent study in twelve countries, sharing increased considerably from 4 to 12 years of age in every country (Samek & others, 2020).

Benevolence can be evident early in life. One study found that even 5-year-olds were inclined to give more to poor than to wealthy individuals, thus indicating that their motivation to help the poor overruled their otherwise dominant inclination to share resources equally (Paulus, 2014). However, in this study 3-year-olds did not share more resources with poor than wealthy individuals. Another study revealed that 8-year-olds were more likely to donate resources to needy peers than were 4-year-olds (Ongley, Nola, & Malti, 2014).

Parental advice and prodding certainly foster standards of sharing, but the give-and-take of peer requests and arguments provides the most immediate stimulation of sharing. Parents can set examples that children carry into their interactions and communication with peers, but parents are not present during all of their children's peer exchanges. The day-to-day construction of fairness standards is done by children in collaboration and negotiation with each other. Over the course of many years and thousands of encounters, children's understanding of concepts such as equality, merit, benevolence, and compromise deepens. With this understanding comes a greater consistency and generosity in children's sharing (Damon, 1988).

How does prosocial behavior change through childhood and adolescence? Prosocial behavior occurs more often in adolescence than in childhood, although examples of caring for others and comforting someone in distress occur even during the preschool years (Eisenberg & Spinrad, 2016).

Why might prosocial behavior increase in adolescence? Cognitive changes involving advances in abstract, idealistic, and logical reasoning as well as increased empathy and emotional understanding likely are involved. With such newfound cognitive abilities, young adolescents increasingly sympathize with members of abstract groups with whom they have little experience, such as people living in poverty in other countries (Eisenberg & Spinrad, 2016). The increase in volunteer opportunities in adolescence also contributes to more frequent prosocial behavior.

Research also indicates that when adolescents engage in prosocial behavior, it is linked to other positive aspects of their development (Donahue, Tillman, & Luby, 2020). For example, a meta-analysis of 55 studies observing individuals from childhood through emerging adulthood concluded that engaging in higher levels of prosocial behavior was related to lower levels of internalizing and externalizing problems (Memmott-Elison & others, 2020).

Are there different types of prosocial behavior? In one study, Gustavo Carlo and his colleagues (2010, pp. 340–341) investigated this question and confirmed the presence of six types of prosocial behavior in young adolescents:

- altruism ("One of the best things about doing charity work is that it looks good.")
- public ("Helping others while I'm being watched is when I work best.")
- emotional ("I usually help others when they are very upset.")
- dire ("I tend to help people who are hurt badly.")
- anonymous ("I prefer to donate money without anyone knowing.")
- compliant ("I never wait to help others when they ask for it.")

In this study, adolescent girls reported more emotional, dire, compliant, and altruistic behavior than did boys, while boys engaged in more public prosocial behavior. Parental monitoring was positively related to emotional, dire, and compliant behavior but not the other types of behavior. Compliant, anonymous, and altruistic prosocial behavior were positively related to religiosity.

Research on prosocial behavior is often conceptualized in a global and unidimensional manner. The study by Carlo and others (2010) illustrates the important point that in thinking about and studying prosocial behavior it is important to consider its dimensions.

Two aspects of prosocial behavior are forgiveness and gratitude. **Forgiveness** is an aspect of prosocial behavior that occurs when the injured person releases the injurer from possible behavioral retaliation (Kong & others, 2020). In one investigation, individuals from the fourth grade through college and adulthood were asked questions about forgiveness (Enright, Santos, & Al-Mabuk, 1989). The individuals were especially swayed by peer pressure in their willingness to forgive others. Also, a recent study of Chinese adolescents revealed that empathy played an important role in motivating forgiveness following an offender's transgression (Ma & Jiang, 2020). Further, two recent studies found that forgiveness of others was associated with a lower risk of suicidal behavior in adolescents (Dangel, Webb, & Hirsch, 2018; Quintana-Orts & Rey, 2018). And a study of older adults revealed that women were more likely to forgive than men, people were more likely to forgive family members than non-family members, and forgiveness was more likely to be extended to people who were still alive than to those who were dead (Hantman & Cohen, 2010).

Gratitude is a feeling of thankfulness and appreciation, especially in response to someone doing something kind or helpful (Enright & Song, 2020). Recent research indicates that other-praising gratitude expressions improve relationships (Weiss, Burgmer, & Lange, 2020). Also, in a study of middle school students, a higher level of gratitude was linked to a higher level of purpose (Malin, Liauw, & Damon, 2017). In another study, gratitude was linked to a number of positive aspects of development in young adolescents, including satisfaction with one's family, optimism, and prosocial behavior (Froh, Yurkewicz, & Kashdan, 2009). And a recent study of adolescents found that having the character strength of gratitude increased their prosocial behavior and peer acceptance (Lavy & Benish-Weisman, 2021).

In addition, a longitudinal study assessed the gratitude of adolescents at 10 to 14 years of age (Bono, 2012). Four years after the initial assessment, the most grateful adolescents (top 20 percent) had a stronger sense of the meaning of life, were more satisfied with their life, were happier and more hopeful, had a lower level of negative emotions, and were less depressed than the least grateful students (bottom 20 percent). Further, a recent study of adolescents found that both gratitude and forgiveness were linked to a lower level of reactive and proactive aggression through their connection to self-control (Garcia-Vazquez & others, 2020). Also, a recent study of U.S. and Japanese middle-aged adults indicated that higher gratitude was linked to positive psychological functioning (life satisfaction, anger control, and support given to one's social network, for example) and lower gratitude was related to negative psychological functioning (perceived stress, social anxiety, and loneliness, for example) (Srirangarajan & others, 2020). And in another recent study, older adults who reflected more on important lessons life had taught them were more likely to forgive others, which in turn boosted their positive attitudes toward aging, life satisfaction, hope, and self-esteem (Bryant, Osowski, & Smith, 2021). In sum, given the increasing concern that we live in a world where too often people fail to show how appreciative they are of what others have done for them, the research discussed here indicates that individuals who express gratitude benefit in a number of ways (Enright & Song, 2020).

forgiveness An aspect of prosocial behavior that occurs when the injured person releases the injurer from possible behavioral retaliation.

gratitude A feeling of thankfulness and appreciation, especially in response to someone's doing something kind or helpful.

Ninety-eight-year-old volunteer Iva Broadus plays cards with 10-year-old DeAngela Williams in Dallas, Texas. Iva was recognized as the oldest volunteer in the Big Sisters program in the United States. She says that the card-playing helps to keep her memory and thinking skills good and can help DeAngela's as well. *What are some other positive outcomes of volunteering as an older adult?*
Jim Mahoney/Dallas Morning News

Gender and Prosocial Behavior Are there gender differences in prosocial behavior during childhood and adolescence? Research indicates that differences exist (Eisenberg, Spinrad, & Morris, 2013). For example, across childhood and adolescence, females engage in more prosocial behavior than males. The largest gender difference occurs for kind and considerate behavior, with a smaller difference for sharing.

Altruism and Volunteerism in Older Adults In a recent national study, adults aged 65 years and older were more likely than their younger counterparts to volunteer their services (AARP, 2019). In this study, 32 percent of those 65 years and older volunteered on a weekly basis (compared with 22 percent for ages 50 to 64, 16 percent for ages 35 to 49, and 17 percent for ages 18 to 34. In this study, 72 percent of individuals 65 years and older said they volunteered because they want to use their skills or experiences meaningfully (compared with 60 percent or less for younger age groups).

Volunteering is associated with a number of positive outcomes for aging adults (Guiney & Machado, 2018). Recent studies have found that when aging adults volunteer they have better physical health (Burr & others, 2018), have better mental health (Jongenelis & Pettigrew, 2021), have better cognitive functioning (Proulx, Curl, & Ermer, 2018), and are less lonely (Carr, Kail, & Rowe, 2018). For example, a recent study of lesbian and gay older adults revealed that those who volunteered had better physical and mental well-being and less psychological distress than non-volunteers (Lyons & others, 2021).

A common perception is that older adults need to receive help rather than to give help to others. However, might giving help as an older adult be beneficial and even be linked to longevity? In a recent study, of four indices (volunteering, informally helping others through a modest time commitment, attending religious services, and going to social group meetings), the strongest predictor of longevity and lower risk for cardiovascular disease was volunteering (Han & others, 2017).

What are some characteristics of conduct disorder?
Stockdisc/PunchStock

conduct disorder Age-inappropriate actions and attitudes that violate family expectations, society's norms, and the personal or property rights of others.

ANTISOCIAL BEHAVIOR

Most children and adolescents at one time or another act out or do things that are destructive or troublesome for themselves or others. If these behaviors occur often, psychiatrists diagnose them as conduct disorders. If these behaviors result in illegal acts by juveniles, society labels them *delinquents*. Both problems are much more common in males than in females (Mash & Wolfe, 2019).

Conduct Disorder **Conduct disorder** refers to age-inappropriate actions and attitudes that violate family expectations, society's norms, and the personal or property rights of others (Mohan, Yilanli, & Ray, 2021). Children with conduct problems show a wide range of rule-violating behaviors, from swearing and temper tantrums to severe vandalism, theft, and assault (Luo & others, 2021).

As part of growing up, most children and youth break the rules from time to time–they fight, skip school, break curfew, steal, and so on. As many as 50 percent of the parents of 4- to 6-year-old children report that their children steal, lie, disobey, or destroy property at least some of the time (Achenbach, 1997). Approximately 25 percent of children and youth diagnosed with conduct disorder subsequently develop *antisocial personality disorder*, a mental disorder characterized by disregarding the difference between right and wrong, as well as ignoring the rights and feelings of others (Rubin, 2020). Many individuals with this disorder engage in criminal activity.

It has been estimated that up to10 percent of children show serious conduct problems (Rubin, 2020). These children are often described as showing an *externalizing*, or *undercontrolled*, pattern of behavior. Children who show this pattern often are impulsive, overactive, and aggressive and engage in delinquent actions (Mohan, Yilani, & Ray, 2020).

Conduct problems in children are best explained by a confluence of causes, or risk factors, operating over time (Mash & Wolfe, 2019). These include possible genetic inheritance of a difficult temperament, ineffective parenting, and living in a neighborhood where violence is the norm.

Juvenile Delinquency

Closely linked with conduct disorder is **juvenile delinquency,** which refers to actions taken by an adolescent in breaking the law or engaging in behavior that is considered illegal. Like other categories of disorders, juvenile delinquency is a broad concept; legal infractions range from littering to murder. Because the adolescent technically becomes a juvenile delinquent only after being judged guilty of a crime by a court of law, official records do not accurately reflect the number of illegal acts that are committed by juvenile delinquents.

One issue in juvenile justice is whether an adolescent who commits a crime should be tried as an adult (Fine & others, 2017a, b). Some psychologists have proposed that individuals 12 and under should not be evaluated under adult criminal laws and that those 17 and older should be (Cauffman & others, 2015). They also recommend that individuals 13 to 16 years of age be given some type of individualized assessment to determine whether they should be tried in a juvenile court or an adult criminal court.

Frequency

Estimates of the number of juvenile delinquents in the United States are sketchy, but FBI statistics indicate that at least 2 percent of all youth are involved in juvenile court cases. In 2017, there were 818,900 delinquency cases in which juveniles were charged with violating criminal laws—down from 1,400,000 in 2010 but up from 400,000 in 1960 (Hockenberry & Puzzanchera, 2019). Males are more likely to engage in delinquency than are females. However, U.S. government statistics revealed that the percentage of delinquency cases involving females increased from 19 percent in 1985 to 27 percent in 2017 (Hockenberry & Puzzanchera, 2019).

Developmental Changes and Pathways

As adolescents become emerging adults, do their rates of delinquency and crime change? Research indicates that rates of theft, property damage, and physical aggression decrease from 18 to 26 years of age (Schulenberg & Zarrett, 2006). The peak ages for property damage are 16 to 18 years for males and 15 to 17 years for females. However, the peak ages for violence are 18 to 19 years for males and 19 to 21 years for females (Farrington, 2004). In a British longitudinal study of males from 8 to 61 years of age, the childhood factors that best predicted which individuals would have criminal careers lasting at least 20 years were harsh discipline, poor parental supervision, parental conflict, and a convicted father (Farrington, 2020). In another longitudinal study, the Pittsburgh Youth Study, the adolescent factors that best predicted which boys were most likely to be in the worst category of criminal offenders through their thirties were frequency of sexual activity, school problems, and having friends who were a bad influence (Ahonen & others, 2020).

A distinction is made between early-onset (before age 11) and late-onset (after age 11) antisocial behavior. Early-onset antisocial behavior is associated with more negative developmental outcomes than late-onset antisocial behavior (Schulenberg & Zarrett, 2006). Early-onset antisocial behavior is more likely to persist into emerging adulthood and is associated with higher rates of mental illness and relationship problems (Stouthamer-Loeber & others, 2004).

One individual whose goal is to reduce juvenile delinquency and help at-risk adolescents cope more effectively with their lives is Rodney Hammond. To read about his work, see the *Connecting with Careers* profile.

Causes of Delinquency

What causes delinquency? Many causes have been proposed, including heredity, identity problems, community influences, and family experiences. Erik Erikson (1968), for example, noted that adolescents may choose a negative identity if their development has restricted them from acceptable social roles or made them feel that they cannot measure up to the demands placed on them. Adolescents with a negative identity may find support for their delinquent image among peers, reinforcing the negative identity. Erikson viewed delinquency as an attempt to establish an identity, even though it is a negative one.

Although delinquency is less exclusively a phenomenon of lower socioeconomic status today than it was in the past, some characteristics of lower-SES culture might promote delinquency (Gold, 2020). A recent study found that neighborhood poverty was linked to delinquency in adolescence, especially through maternal stress and adverse child experiences (Wang, Choi, & Shin, 2020). The norms of many lower-SES peer groups and gangs are antisocial, or counterproductive to the goals and norms of society at large. Getting into and staying out of trouble are prominent features of life for some adolescents in low-income neighborhoods. Adolescents from low-income backgrounds may sense that they can gain attention and status by performing antisocial actions. Furthermore, adolescents in communities with high crime rates observe many models who engage in criminal activities. Quality schooling, educational funding, and organized neighborhood activities may be lacking in these communities (Nishina & Bellmore, 2018). Also,

juvenile delinquency Actions taken by an adolescent in breaking the law or engaging in illegal behavior.

connecting with careers

Rodney Hammond, Health Psychologist

Rodney Hammond described how his college experiences influenced his choice of career: "When I started as an undergraduate at the University of Illinois Champaign-Urbana, I hadn't decided on my major. But to help finance my education, I took a part-time job in a child development research program sponsored by the psychology department. There, I observed inner-city children in settings designed to enhance their learning. I saw first-hand the contribution psychology can make, and I knew I wanted to be a psychologist" (American Psychological Association, 2003, p. 26).

After earning his undergraduate degree, Rodney Hammond went on to obtain a doctorate in school and community psychology with a focus on children's development. For a number of years, he trained clinical psychologists at Wright State University in Ohio and directed a program to reduce violence in ethnic minority youth. There, he and his associates taught at-risk youth how to use social skills to effectively manage conflict and to recognize situations that could lead to violence. Hammond became the first Director of the Division of Violence Prevention at the Centers for Disease Control and Prevention in Atlanta. He is currently Adjunct Professor of Human Development and Counseling at the University of Georgia, following his retirement from CDC.

What are some factors that influence whether adolescents will become delinquents?
Fertnig/iStock/Getty Images

one study found that youth whose families had experienced repeated poverty were more than twice as likely to be delinquent at 14 and 21 years of age (Najman & others, 2010).

Certain characteristics of families are also associated with delinquency (Kapetanovic & Skoog, 2021). Parents of delinquents are less skilled in discouraging antisocial behavior and in encouraging prosocial behavior than are parents of nondelinquents. Parental monitoring of adolescents is especially important in determining whether an adolescent becomes a delinquent (Henneberger & others, 2013). One study found that early parental monitoring in adolescence and ongoing parental support were linked to a lower incidence of criminal behavior in emerging adulthood (Johnson & others, 2011). Also, one study found that low rates of delinquency from 14 to 23 years of age were associated with an authoritative parenting style (Murphy & others, 2012). Further, a recent study revealed that parental monitoring was a protective factor against juvenile delinquency for both boys and girls but was a stronger influence for girls than boys (Liu & Miller, 2020). And family discord and inconsistent and inappropriate discipline are also associated with delinquency (Capaldi & Shortt, 2003).

Few studies demonstrate in an experimental design that changing parenting practices in childhood is related to a reduced incidence of juvenile delinquency in adolescence. However, one study by Marion Forgatch and her colleagues (2009) randomly assigned divorced mothers with sons to an experimental group (mothers received extensive parenting training) and a control group (mothers received no parenting training) when their sons were in the first to third grades. The parenting training consisted of 14 parent group meetings that especially focused on improving parenting practices with their sons (skill encouragement, limit setting, monitoring, problem solving, and positive involvement). Best practices for emotion regulation, managing interparental conflict, and talking with children about divorce also were included in the sessions. Improved parenting practices and reduced contact with deviant peers were linked with lower rates of delinquency in the experimental group than in the control group at a nine-year follow-up assessment.

Family therapy is often effective in reducing delinquency (Amani & others, 2018). A research meta-analysis found that of five program types (case management, individual treatment, youth court, restorative justice, and family treatment), family treatment was the only type that was

linked to reduced recidivism for juvenile offenders (Schwalbe & others, 2012). Also, in one study, family therapy improved juvenile court outcomes beyond what was achieved in non-family-based treatment, especially in reducing criminal behavior and rearrests (Dakof & others, 2015).

An increasing number of studies have found that siblings can have a strong influence on delinquency (Bank, Burraston, & Snyder, 2004). In one study, high levels of hostile sibling relationships and delinquency of older siblings were linked with younger sibling delinquency in both brother pairs and sister pairs (Slomkowski & others, 2001).

Having delinquent peers and friends increases the risk of becoming delinquent. In a recent study, associating more with prosocial peers at 12 years of age predicted a decline in property offending delinquency a year later, associating less with prosocial peers at 12 years of age predicted an increase in property offending a year later (Walters, 2019). And another recent study found that having a best friend who was delinquent was linked to a higher probability that adolescents would also become delinquent (Levey & others, 2019).

In addition to the influences discussed above, school-related factors are associated with delinquency (Gordon Simons & others, 2018). In a recent research review, lack of academic success and having a learning disability were linked to delinquency (Grigorenko & others, 2019). Also, in a recent study of 11- to 17-year-olds, greater school engagement was linked to committing fewer minor offenses and fewer crimes against persons and property (Lamari-Fisher & Bond, 2021). And a number of cognitive factors such as low self-control, low intelligence, and lack of sustained attention are linked to delinquency (Muftic & Updegrove, 2018). In a recent study of female adolescents, increases in self-control were linked to decreased likelihood of police contact (Hipwell & others, 2018). Further, a recent study in rural China found that low self-control was linked to delinquent behavior in adolescents (Jiang, Chen, & Zhuo, 2020). And recent research indicates that having callous-unemotional personality traits predicts an increased risk of engaging in delinquency for adolescent males (Ray & others, 2017).

Does intervening in the lives of children with early conduct problems help reduce their delinquency risk in adolescence? Fast Track is an intervention that attempts to lower the risk of juvenile delinquency and other problems (Conduct Problems Prevention Research Group, 2007, 2011, 2015; Conduct Problems Prevention Research Group & others, 2019; Kassing & others, 2019; Miller & others, 2011). The average age of the children when the intervention began was 6.5 years. The 10-year intervention consisted of behavior management training of parents, social cognitive skills training of children, reading tutoring, home visitations, mentoring, and a revised classroom curriculum that was designed to increase socioemotional competence and decrease aggression.

Positive outcomes for the intervention occurred as early as the third grade and continued through the ninth grade. For example, in the ninth grade the intervention reduced the likelihood that the highest-risk kindergarten children would develop conduct disorder by 75 percent, attention deficit hyperactivity disorder by 53 percent, and any externalized disorder by 43 percent. Data have been reported through age 25. Findings indicate that the comprehensive Fast Track intervention was successful in reducing youth arrest rates (Conduct Problems Prevention Research Group, 2011). And in a recent study, it was found that for populations with high risk rates as little as one teacher screen taken during kindergarten or the first grade predicted whether males would have adult criminal convictions by age 25 (Kassing & others, 2019).

Review

- How is altruism defined? How does prosocial behavior develop?
- What is conduct disorder? What are key factors in the development of juvenile delinquency?

Connect

- Compare the development of prosocial and antisocial behavior in children. What are your conclusions?

Reflect *Your Own Personal Journey of Life*

- Did you commit acts of delinquency as an adolescent? Most adolescents commit one or more delinquent acts but don't become habitual juvenile delinquents. Reflect on your experiences of either committing juvenile offenses or not committing them, and then review the discussion of likely causes of juvenile delinquency and apply them to your development.

4 Values, Religion, Spirituality, and Meaning in Life

LG4 Characterize the development of values, religion, spirituality, and meaning in life.

Values | Religion and Spirituality | Meaning in Life

James Garbarino (1999) has interviewed a number of young killers. He concludes that nobody really knows precisely why a tiny minority of youth kill, but that the cause might be a lack of a spiritual center. In many of the youth killers he interviewed, Garbarino found a spiritual or emotional emptiness that led them to seek meaning in the dark side of life. Are spirituality and religion important in your life? How much time have you spent thinking about the meaning of life? What are your values?

VALUES

Values are beliefs and attitudes about the way things should be. They involve what is important to us. We attach value to all sorts of things: politics, religion, money, sex, education, helping others, family, friends, career, recognition, self-respect, and so on. We carry with us values that influence our thoughts, feelings, and actions. To think about the values that are most important to you, see Figure 3.

values Beliefs and attitudes about the way things should be.

One way to measure what people value is to ask them what their goals are. Over the past four decades, traditional-aged college students have shown an increased concern for personal well-being and a decreased concern for the well-being of others, especially for the disadvantaged (Stolzenberg & others, 2019). As shown in Figure 4, today's college freshmen are more strongly motivated to be well-off financially and less motivated to develop a meaningful philosophy of

What Are My Values?

Look at the following list of values and think about the extent to which each value characterizes you. Place check marks next to the five values that are most important to you. Then go back over the values you selected and rank order them from 1 to 5, with 1 being the most important.

Values

___Having good friends and getting along with people
___Having a good relationship with a romantic partner
___Having self-respect
___Being well-off financially
___Having a good spiritual or religious life
___Being competent at my work
___Having the respect of others
___Making an important contribution to the world
___Being a good person
___Feeling secure
___Having peace of mind
___Being happy
___Being healthy
___Being intelligent
___Having inner peace
___Living an exciting life

The following values are most important to me:

1.
2.
3.
4.
5.

FIGURE 3

WHAT ARE MY VALUES?

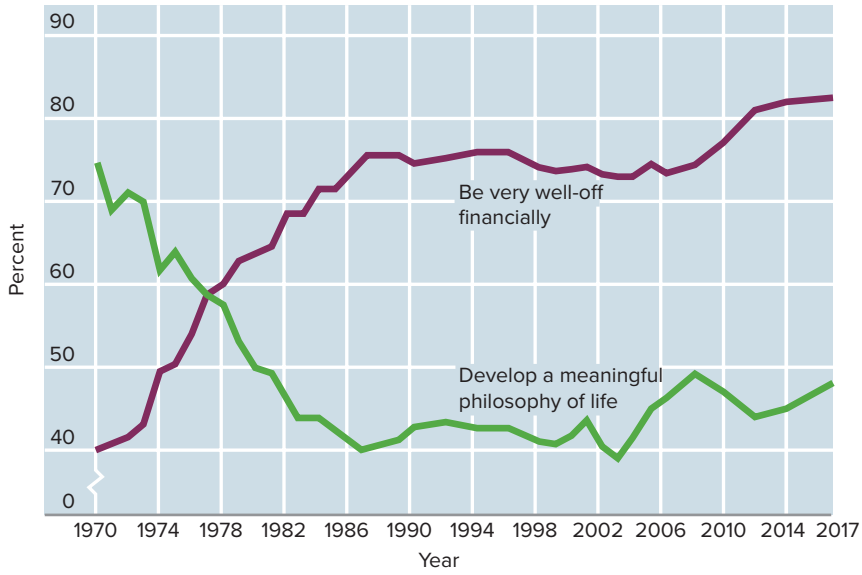

FIGURE 4

CHANGING FRESHMAN LIFE GOALS, 1970 TO 2017. Since 1970, a significant change has occurred in the life goals of college freshmen. A far greater percentage of today's college freshmen state that an "essential" or "very important" life goal is to be very well-off financially, and far fewer state that developing a meaningful philosophy of life is an "essential" or "very important" life goal.

life than were their counterparts of 40 or even 20 years ago. In 2017, 82.5 percent of students (the highest percentage ever in this survey) viewed becoming very well-off financially as an "essential" or a "very important" objective, compared with only 42 percent in 1971.

There are, however, some signs that U.S. college students are shifting toward a stronger interest in promoting the welfare of society. In the survey just described, interest in developing a meaningful philosophy of life increased from 39 percent to 48.1 percent of U.S. freshmen from 2001 through 2017 (Stolzenberg & others, 2019) (see Figure 4). Also in this survey, the percentage of college freshmen who said the chances are very good that they will participate in volunteer or community service programs increased from 18 percent in 1990 to 36.7 percent in 2017 (Stolzenberg & others, 2019).

Our discussion of values corresponds to William Damon's (2008) view proposed in *The Path to Purpose: Helping Children Find Their Calling in Life*. Damon concluded that a major difficulty confronting today's youth is their lack of a clear sense of what they want to do with their lives–that too many youth are essentially "rudderless." Damon (2008, p. 8) found that only about 20 percent of 12- to 22-year-olds in the United States expressed "a clear vision of where they want to go, what they want to accomplish in life, and why." He argues that their goals and values too often focus on the short term, such as getting a good grade on a test this week and finding a date for a dance, rather than developing a plan for the future based on positive values (Damon & Malin, 2020). Adults can guide young people to develop more purposeful values by posing questions like these: "What's most important in your life? Why do you care about those things? What does it mean to be a good person?" (Damon, 2008, p. 135).

RELIGION AND SPIRITUALITY

In Damon's (2008) view, one long-standing avenue for discovering purpose in life is religion. Religion and spirituality play important roles in the lives of many people around the world (Cesari, 2021).

Is religion different from spirituality? Pamela King and her colleagues (King & Boyatzis, 2015; Kim, Lee, & King, 2021; King & others, 2021a, b; King, Vaughn, & Merola, 2020) provide the following distinctions:

- **Religion** is an organized set of beliefs, practices, rituals, and symbols that increases an individual's connection to a sacred or transcendent other (God, higher power, or ultimate truth).

As an adolescent, Nina Vasan founded ACS Teens, a nationwide network of student volunteers who support the mission of the American Cancer Society. Through an online network, ACS Teens served as an incubator for social change: it trained, mobilized, mentored, and united teenagers to find creative solutions to improving health in their communities and supporting the ACS through advocacy, education, fundraising, and service. ACS Teens volunteers helped raise hundreds of thousands of dollars for cancer research, helped change state tobacco laws, and led educational programs to prevent cancer. Nina completed her MD degree at Harvard University Medical School and currently is the Director of Brainstorm: The Stanford Laboratory for Mental Health Innovation and Entrepreneurship. In 2013, she published her first book (with co-author Jennifer Przybylo), *Do Good Well.* The book reflects Nina's motivation to get others involved in leadership and to encourage them to take action in improving people's lives. *Do Good Well* became a #1 Amazon Best Seller.

Religion enlightens, terrifies, subdues; it gives faith, inflicts remorse, inspires resolutions, and inflames devotion.

–Henry Newman
English Churchman and Writer, 19th Century

religion An organized set of beliefs, practices, rituals, and symbols that increases an individual's connection to a sacred or transcendent other (God, higher power, or higher truth).

religiousness The degree of affiliation with an organized religion, participation in prescribed rituals and practices, connection with its beliefs, and involvement in a community of believers.

spirituality Experiencing something beyond oneself in a transcendent manner and living in a way that benefits others and society.

- **Religiousness** refers to the degree of affiliation with an organized religion, participation in its prescribed rituals and practices, connection with its beliefs, and involvement in a community of believers.
- **Spirituality** involves experiencing something beyond oneself in a transcendent manner and living in a way that benefits others and society.

What developmental changes characterize the influence of religion, religiousness, and spirituality in people's lives?

Childhood, Adolescence, and Emerging Adulthood Societies use many methods—such as Sunday schools, parochial education, and parental teaching—to ensure that people will carry on a religious tradition. In a national study, 63 percent of parents with children at home said they pray or read Scripture with their children, and 60 percent reported that they send their children to religious education programs (Pew Research Center, 2008). Does this religious socialization work? In many cases it does (Paloutzian, 2000).

In general, individuals tend to adopt the religious teachings of their upbringing. In a recent national survey, 48 percent of adolescents said they have "all the same" religious beliefs as their parents (Diamant & Sciupac, 2020). Also in this survey, 40 percent of adolescents reported that they attend religious services with both parents. However, if a religious change or reawakening occurs, it is most likely to take place during adolescence, although it is important to consider the quality of the parent-adolescent relationship. Adolescents who have a positive relationship with their parents or are securely attached to them are likely to adopt the religious orientation of their parents (Dudley, 1999). Adolescents who have a negative relationship with their parents or are insecurely attached to them may disaffiliate from religion or seek religion-based attachments that are missing in their family system (Streib, 1999).

Religious issues are important to many adolescents and emerging adults, but during the twenty-first century religious interest among adolescents and emerging adults has declined. In a recent national study of American college freshmen, 69.2 percent said they had attended religious services frequently or occasionally during their senior year in high school in 2017, down from 73 percent in 2010 and down from a high of 85 percent in 1997 (Stolzenberg & others, 2019).

Many children and adolescents show an interest in religion, and many religious institutions created by adults (such as this Muslim school in Malaysia) are designed to introduce them to religious benefits and ensure that they will carry on a religious tradition.
Lano Lan/Shutterstock

A developmental study revealed that religiousness declined from 14 to 20 years of age in the United States (Koenig, McGue, & Iacono, 2008) (see Figure 5). In this study, religiousness was assessed with items such as frequency of prayer, frequency of discussing religious teachings, frequency of deciding moral actions for religious reasons, and the overall importance of religion in everyday life. As indicated in Figure 5, more change in religiousness occurred from 14 to 18 years of age than from 20 to 25 years of age. Also, attending religious services was highest at 14 years of age, declined from 14 to 18 years of age, and increased at 20 years of age. More change occurred in attending religious services than in religiousness. Another study found that across the first three semesters of college, students were less likely to attend religious services or engage in religious activities (Stoppa & Lefkowitz, 2010).

Analysis of the World Values Survey of 18- to 24-year-olds revealed that emerging adults in less developed countries were more likely to be religious than their counterparts in more developed countries (Lippman & Keith, 2006). For example, emerging adults' reports of religion being very important in their lives ranged from a low of 0 in Japan to a high of 93 percent in Nigeria, and belief in God ranged from a low of 40 percent in Sweden to a high of 100 percent in Pakistan.

Religion and Cognitive Development Adolescence and emerging adulthood can be especially important junctures in religious development (King & others, 2021a, b; King, Vaughn, & Merola, 2020). Even if children have been indoctrinated into a religion by their parents, because of advances in their cognitive development adolescents and emerging adults may question what their own religious beliefs truly are.

Many of the cognitive changes thought to influence religious development involve Piaget's cognitive developmental stages. More so than in childhood, adolescents think abstractly, idealistically, and logically. The increase in abstract thinking lets adolescents consider various religious and spiritual concepts. For example, an adolescent might ask how a loving God can possibly exist given the extensive suffering of many people in the world (Good & Willoughby, 2008). Adolescents' increasingly idealistic thinking provides a foundation for thinking about whether religion provides the best route to a better, more ideal world (Scarlett, 2020). And adolescents' increased capacity for logical reasoning gives them the ability to develop hypotheses and systematically sort through different answers to spiritual questions (Good & Willoughby, 2008).

Religion and Identity Development During adolescence and especially during emerging adulthood, identity development becomes a central focus (Syed, Pasupathi, & McLean, 2020). Adolescents and emerging adults look for answers to questions like these: "Who am I? What am I all about as a person? What kind of life do I want to lead?" As part of their search for identity, adolescents and emerging adults begin to grapple in more sophisticated, logical ways with such questions as "Why am I on this planet? Is there really a God or higher spiritual being, or have I just been believing what my parents and the church imprinted in my mind? What really are my religious views?" An analysis of the link between identity and spirituality concluded that adolescence and adulthood can serve as gateways to a spiritual identity that "transcends, but not necessarily excludes, the assigned religious identity in childhood" (Templeton & Eccles, 2006, p. 261).

A study of Latinx, African American, Asian, and non-Latinx White adolescents revealed that their religious identity remained stable across high school but that their religious participation declined (Lopez, Huynh, & Fuligni, 2011). In this study, Latinx and Asian adolescents had the highest levels of religious identity, while Latinx adolescents had the highest level of religious participation.

Religion and Sexuality in Adolescence and Emerging Adulthood One area of religion's influence on adolescent and emerging adult development involves sexual activity. Although variability and change in church teachings make it difficult to generalize about religious doctrines, most churches discourage premarital sex. Thus, the degree of adolescent and emerging adult participation in religious organizations may be more important than affiliation with a specific religion as a determinant of premarital sexual attitudes and behavior. Adolescents and emerging adults who frequently attend religious services are likely to hear messages about abstaining from sex until marriage. Involvement of adolescents and emerging adults in religious organizations also enhances the probability that they will become friends with

adolescents who hold restrictive attitudes toward premarital sex. One study revealed that adolescents with high religiosity were less likely to have had sexual intercourse (Gold & others, 2010). And in a recent study of African American adolescent girls, those who reported that religion was of low or moderate importance to them had a younger sexual debut than their counterparts who indicated that religion was extremely important to them (George Dalmida & others, 2018).

The Positive Role of Religion in Adolescents' Lives Researchers have found that various aspects of religion are linked with positive outcomes for adolescents (King, Schnitker, & Houltberg, 2020). A number of studies have found that adolescents who are involved in religious institutions are more likely to engage in service learning than their counterparts who don't participate in religious institutions (Hart, 2020). Religion plays a role in adolescents' health and has an influence on whether they engage in problem behaviors. For example, a meta-analysis found that spirituality/religiosity was positively related to adolescents' well-being and self-esteem (Yonker, Schnabelrauch, & DeHaan, 2012). Also, in a recent study, religiosity was linked to delayed onset of alcohol use, more so for adolescent girls than boys (Barry, Valdez, & Russell, 2020). Further, across three countries (England, Scotland, and Canada), adolescents who reported having a higher level of spirituality were more likely to have positive health outcomes (Brooks & others, 2018).

Adulthood and Aging What roles do religion and spirituality play in the lives of adults? Is religion related to adults' health? Is there a point in adult development at which understanding of the meaning of life increases? How do religious beliefs affect the lives of older adults?

Religion and Spirituality in Adulthood How religious are Americans? A national poll of more than 35,000 U.S. adults found that 92 percent said they believe in God, 75 percent reported that they pray at least weekly and 58 percent said they pray every day, 56 percent said that religion is very important, and 39 percent indicated that they attend religious services at least weekly (Pew Research Center, 2008). However, in a later national poll, those who said that "religion is very important" had dropped to 50 percent (Pew Research Center, 2015). And a growing percentage of people in the United States consider themselves spiritual but not religious. In a 2017 national poll, 27 percent said they are spiritual but not religious, up 8 percentage points in five years (Lipka & Gecewicz, 2017). This trend is broad-based, occurring among males and females, different ages and educational levels, and different ethnic groups.

Gender and ethnic differences characterize religious interest and participation. Females have consistently shown a stronger interest in religion than males have (Idler, 2006). In a national U.S. study, 60 percent of women and 47 percent of men said that religion was very important in their lives (Pew Research Center, 2016). Compared with men, women participate more in both organized and personal forms of religion, are more likely to believe in a higher power or presence, and are more likely to feel that religion is an important dimension of their lives. Regarding ethnicity, African Americans and Latinxs show higher rates of religious participation than do non-Latinx White Americans (Idler, 2006).

In thinking about religion and adult development, it is important to consider individual differences. Religion is a powerful influence in some adults' lives, whereas it plays little or no role in other adults' lives (Myers, 2000). Further, the influence of religion in people's lives may change as they develop. For example, in a longitudinal investigation, some individuals who had been strongly religious in their early-adult years became less so in middle age, while others became more religious in middle age (Clausen, 1993).

What roles do religion and spirituality play in adults' lives?
A katz/Shutterstock

Religion and Health How might religion be linked to physical health? Some cults and religious sects encourage behaviors that are damaging to health, such as ignoring sound medical advice. For individuals in the religious mainstream, researchers increasingly find that religion is positively linked to health (Park & Lee, 2020; Saad & de Medeiros, 2021). For example, in a recent Danish study, participating in a religious organization and praying were associated with fewer risk factors for engaging in an unhealthy lifestyle (Herold & others, 2021). In another study, spiritual well-being predicted which heart failure patients would still be alive five years later (Park & others, 2016). Also, another study found that older adults who had a higher level of religious identification were less likely to be depressed (Ysseldyk, Haslam, & Haslam, 2013). In addition, a number of studies have found a positive association between religious participation and longevity (Kim, Smith, & Kang, 2015).

Why might religion be linked to physical health?
Blend Images-Hill Street Studios/Getty Images

Why might religion promote physical health? There are several possible answers:

- *Lifestyle issues*. For example, religious individuals have lower rates of drug use than their nonreligious counterparts (Barry, Valdez, & Russell, 2020).
- *Social networks*. Well-connected individuals have fewer health problems (Chen & others, 2020). Religious groups, meetings, and activities provide social connectedness for individuals.
- *Coping with stress*. Religion offers a source of comfort and support when individuals are confronted with stressful events (Krause, 2019).

Religious and spiritual counselors often advise people about mental health and coping (Ogorek & Isaacson, 2020). To read about the work of one religious counselor, see the *Connecting with Careers* profile. In the *Connecting Development to Life* interlude we further explore links between religion and coping.

connecting with careers

Gabriel Dy-Liacco, Professor and Pastoral Counselor

Gabriel Dy-Liacco is a professor in religious and pastoral counseling at Regent University in the Virginia Beach, Virginia, area. He obtained his Ph.D. in pastoral counseling from Loyola College in Maryland and also has experience as a psychotherapist in mental health settings such as a substance-abuse program, military family center, psychiatric clinic, and community mental health center. Earlier in his career he was a pastoral counselor at the Pastoral Counseling and Consultation Centers of Greater Washington, DC, and taught at Loyola University in Maryland. As a pastoral counselor, he works with adolescents and adults to help them address the aspects of their lives that they show the most concern about—psychological, spiritual, or the interface of both. Having lived in Peru, Japan, and the Philippines, he brings considerable multicultural experience to teaching and counseling settings.

Dr. Gabriel Dy-Liacco

connecting development to life

Religion and Coping

Is religion linked to individuals' ability to cope with stress? Some psychologists have categorized prayer and religious commitment as defensive coping strategies, arguing that they are less effective in helping individuals cope than are life-skill, problem-solving strategies. However, religious coping often benefits individuals during times of high stress (Krause, 2019; Rosmarin, Pargament, & Koenig, 2021). For example, one study found that coping styles that relied on collaboration with others and turning to religious groups were more strongly related to improved psychological adjustment than a self-directed coping style (Ross & others, 2009). And in a study of veterans with combat exposure, negative religious coping was associated with higher rates of posttraumatic stress disorder (PTSD symptoms), while positive religious/spiritual coping was linked to higher perceived posttraumatic growth (PPTG) symptoms (Park & others, 2016).

How is religion linked to the ability to cope with stress?
Image Source/Alamy Stock Photo

A recent interest in linking religion and coping focuses on **meaning-making coping,** which involves drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of high levels of stress such as when a loved one dies. In Crystal Park's (2010, 2013) view, individuals who are religious experience more disruption of their beliefs, values, and goals immediately after the death of a loved one than do individuals who are not religious. Initially, religion is linked with more depressed feelings about a loved one's death. Over time, however, as religious individuals search for meaning in their loss, they often become less depressed and show better adjustment. Thus, religion can serve as a meaning system through which bereaved individuals are able to reframe their loss and even find avenues of personal growth (George & Park, 2017).

In sum, various dimensions of religiousness can help some individuals cope more effectively with challenges that arise (King, 2020). Religious beliefs can shape a person's psychological perception of pain or disability. Religious cognitions can play an important role in maintaining hope and stimulating motivation toward recovery (Gall & Bilodeau, 2020). Because of its effectiveness in reducing distress, religious coping can help prevent denial of the problem and thus facilitate early recognition and more appropriate health-seeking behavior. Religion also can forestall the development of anxiety and depression by promoting communal or social interaction (Pandya, 2018). Houses of religious worship are a readily available, acceptable, and inexpensive source of support for many individuals, especially the elderly. The socialization provided by religious organizations can help prevent isolation and loneliness (Peteet, Zaben, & Koenig, 2019).

How would you explain successful coping strategies in those who are not religious? How is religion linked to the ability to cope with stress? What characterizes the search for meaning in life?

Religion in Older Adults In many societies around the world, older adults are the spiritual leaders in their churches and communities. For example, in the Catholic Church, more popes have been elected during their eighties than in any other 10-year period of the human life span.

The religious patterns of older adults have increasingly been studied (Krause, 2019). In a study of individuals from their early thirties through their early seventies, a significant increase in spirituality occurred between late middle adulthood (mid-fifties/early sixties) and late adulthood (late sixties/mid-seventies) (Wink & Dillon, 2002) (see Figure 6). The spirituality of women increased more than that of men. In this study, spirituality in late adulthood was linked with religiosity in early adulthood (thirties). This finding supports the idea that early religious involvement predisposes individuals to engage in further spiritual development. And one survey found that 77 percent of 30- to 49-year-olds and 84 percent of 50- to 64-year-olds reported having a religious affiliation (compared with 67 percent of 18- to 29-year-olds and 90 percent of adults 90 years of age and older) (Pew Research Center, 2012).

Individuals over 65 years of age are more likely than younger people to say that religious faith is the most significant influence in their lives, that they try to put religious faith into

meaning-making coping Drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of high stress such as when a loved one dies.

practice, and that they attend religious services (Gallup & Bezilla, 1992). A study of more than 500 African Americans 55 to 105 years of age revealed that the majority had a strong identification with religious institutions and high levels of attendance and participation in religious activities (Williams, Keigher, & Williams, 2012).

Is religion related to a sense of well-being and life satisfaction in old age? In one study, older adults' self-esteem was highest when they had a strong religious commitment and lowest when they had little religious commitment (Krause, 1995). In another study, older adults who derived a sense of meaning in life from religion had higher levels of life satisfaction, self-esteem, and optimism (Krause, 2003). Also, in one study, older adults who reported having a higher level of spirituality had more resilience in the face of stressful and difficult circumstances (Vahia & others, 2011). And in another study, dementia caregivers who had a higher level of religiosity/spirituality had fewer depressive symptoms their counterparts who had a lower level of religiosity/spirituality (Yoon & others, 2016).

Is religion linked to older adults' health and longevity? In a recent study, older adults with stronger religiosity were less depressed and had longer telomere length on their chromosomes (Wang & others, 2020). Also, a recent study of older adults found that those who regularly attended religious services lived longer than their counterparts who did not attend these services (Idler & others, 2017).

Religion can meet some important psychological needs in older adults, helping them to face impending death, to find and maintain a sense of meaning in life, and to accept the inevitable losses of old age (Victor & Treschuk, 2020). Also, socially, the religious community can serve many functions for older adults, such as providing social activities, social support, and the opportunity to assume teaching and leadership roles.

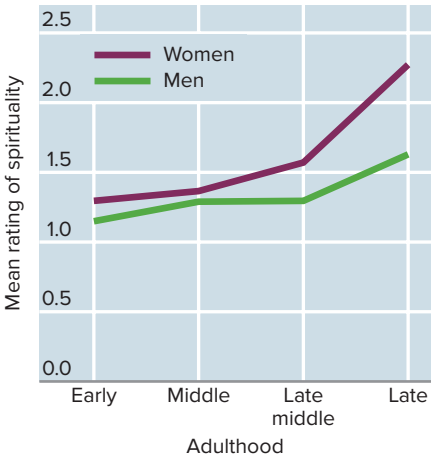

FIGURE 6

LEVEL OF SPIRITUALITY IN FOUR ADULT AGE PERIODS. In a longitudinal study, the spirituality of individuals in four different adult age periods—early (thirties), middle (forties), late middle (mid-fifties/early sixties), and late (late sixties/early seventies) adulthood—was assessed (Wink & Dillon, 2002). Based on responses to open-ended questions in interviews, the spirituality of the individuals was coded on a 5-point scale, with 5 being the highest level of spirituality and 1 the lowest.

MEANING IN LIFE

Austrian psychiatrist Viktor Frankl's mother, father, brother, and wife died in the concentration camps and gas chambers in Auschwitz, Poland. Frankl survived the concentration camp and went on to write about finding meaning in life. In his book, *Man's Search for Meaning*, Frankl (1984) emphasized each person's uniqueness and the finiteness of life. He believed that examining the finiteness of our existence and the certainty of death adds meaning to life. If life were not finite, said Frankl, we could spend our life doing just about whatever we pleased because time would continue forever.

Frankl said that the three most distinct human qualities are spirituality, freedom, and responsibility. Spirituality, in his view, does not have a religious underpinning. Rather, it refers to a human being's uniqueness—of spirit, philosophy, and mind. Frankl proposed that people need to ask themselves such questions as why they exist, what they want from life, and what their life means.

It is in middle adulthood that individuals begin to be faced with death more often, especially the deaths of parents and other older relatives. Also faced with fewer years ahead of them than behind them, many individuals in middle age begin to ask and evaluate the questions that Frankl proposed. And, as we indicated in the discussion of religion and coping, meaning-making coping is especially helpful in times of chronic stress and loss. Also, in a recent U.S. study, when describing what provides them with a sense of meaning in life, 69 percent said family, 34 percent said career, and 20 percent said spirituality and faith (Pew Research Center, 2018).

Researchers are increasingly studying the factors involved in a person's exploration of meaning in life and striving to determine whether developing a sense of meaning in life is linked to positive developmental outcomes. Many individuals state that religion played an important role in increasing their exploration of meaning in life. Studies also suggest that individuals who have found a sense of meaning in life are more physically healthy, happier, and experience less depression than their counterparts who report that they have not discovered meaning in life (Hooker, Post, & Sherman, 2020).

Having a sense of meaning in life can lead to clearer guidelines for living one's life and enhanced motivation to take care of oneself and reach goals (Zhang, 2019). A higher level of meaning in life also is linked to a higher level of psychological well-being and physical health (Deb & others, 2020). For example, recent research indicates that meaning in life can reduce psychological distress (Yu & others, 2020) and facilitate recovery from mental illness (Jun & Yun, 2020).

What characterizes the search for meaning in life?
Eric Audras/Onoky/Getty Images

Roy Baumeister and Kathleen Vohs (2002, pp. 610–611) argue that the quest for a meaningful life can be understood in terms of four main needs for meaning that guide how people try to make sense of their lives:

- *Need for purpose*. "Present events draw meaning from their connection with future events." Purposes can be divided into (1) goals and (2) fulfillments. Life can be oriented toward a future anticipated state, such as living happily ever after or being in love.
- *Need for values*. This "can lend a sense of goodness or positive characterization of life and justify certain courses of action. Values enable people to decide whether certain acts are right or wrong." Frankl's (1984) view of meaning in life emphasized value as the main form of meaning that people need.
- *Need for a sense of efficacy*. This involves the "belief that one can make a difference. A life that had purposes and values but no efficacy would be tragic. The person might know what is desirable but could not do anything with that knowledge." With a sense of efficacy, people believe that they can control their environment, which has positive physical and mental health benefits (Bandura, 2012).
- *Need for self-worth*. Most individuals want to be good, worthy persons. Self-worth can be pursued individually, such as finding out that one is very good at doing something, or collectively, as when people gain self-esteem from belonging to a group or category of people.

Moral Development, Values, and Religion

1 Domains of Moral Development

LG1 Discuss theory and research on moral thought, behavior, feeling, personality, and domains.

What Is Moral Development?

Moral Thought

- Moral development involves changes in thoughts, feelings, and behaviors regarding right and wrong. Moral development has intrapersonal and interpersonal dimensions.
- Piaget distinguished between the heteronomous morality of younger children and the autonomous morality of older children.
- Kohlberg developed an influential theory of moral reasoning. He documented three levels in the development of moral reasoning: preconventional, conventional, and postconventional. Research subsequently documented that these levels were not only related to age but also to diverse social experiences. Influences on the development of moral reasoning include cognitive maturation, cognitive conflict, peer relations, and perspective taking.
- Criticisms of Kohlberg's theory have been made, especially by Gilligan, who advocates a stronger care perspective. Other criticisms focus on the inadequacy of moral reasoning to predict moral behavior, the intuitiveness of moral thought, the role of emotion, and cultural and family influences.

Moral Behavior

- The processes of reinforcement, punishment, and imitation have been used to explain the acquisition of moral behavior, but they provide only a partial explanation. Situational variability is stressed by behaviorists. Cognitions can play a role in resisting temptation and practicing self-control. A social cognitive theory of morality emphasizes a distinction between moral competence and moral performance.

Moral Feeling

- In Freud's theory, the superego is the moral branch of personality. The superego consists of the ego ideal and the conscience. According to Freud, guilt is the foundation of children's moral behavior. Empathy is an important aspect of moral feelings, and it changes developmentally. In the contemporary perspective, both positive and negative feelings contribute to moral development.

Moral Personality

- Recently, there has been a surge of interest in studying moral personality. This interest has focused on moral identity, moral character, and moral exemplars.
- People who have a moral identity value moral notions and commitments to such an extent that behaving in a manner that violates this moral commitment would place the integrity of the self at risk.
- Moral character involves having strong convictions, persisting in the face of adversity, and overcoming distractions and obstacles. Moral character also means having virtues such as honesty, truthfulness, loyalty, and compassion.
- Moral exemplars' identity, character, and virtues reflect moral commitment and excellence.

Social Domain Theory

- Social domain theory states that there are different domains of social knowledge and reasoning, including moral, social conventional, and personal domains.

2 Contexts of Moral Development

LG2 Explain how parents, schools, and culture influence moral development.

Parenting

- Warmth and responsibility in mutual obligations of parent-child relationships provide important foundations for the child's positive moral growth. Moral development can be advanced by these parenting strategies: being warm and supportive rather than punitive; providing opportunities to learn about others' perspectives and feelings; involving children in family decision making; modeling moral behaviors; averting misbehavior before it takes place; and engaging in conversational dialogue related to moral development.

Schools

- The hidden curriculum, initially described by Dewey, is the distinctive moral atmosphere that is present in each school. Contemporary approaches to moral education include character education, service learning, and integrative ethical education. Cheating is a moral education concern and can take many forms. Various situational aspects influence whether students will cheat.

Culture

- Some aspects of morality such as honesty are endorsed across most cultures, but other aspects of morality differ, as shown in comparisons of WEIRD (Western, Educated, Industrialized, Rich, and Democratic) and non-WEIRD cultures. Also, differences can occur within a particular culture, as indicated by comparisons of higher- and lower-SES families. Recently, research has focused on family socialization of moral development, such as the emphasis placed on familism in Mexican American and Latinx cultures.

3 Prosocial and Antisocial Behavior

LG3 Describe the development of prosocial and antisocial behavior.

Prosocial Behavior

- Altruism, which is an unselfish interest and voluntary effort in helping another person, and reciprocity often motivate prosocial behaviors (behaviors intended to help others) such as sharing.
- Recent research has focused on whether infants and toddlers have moral awareness and can engage in prosocial behavior. Damon described a sequence through which children develop their understanding of fairness and begin to share with others more consistently. Peers play a key role in this development.
- Altruism is linked to having a longer life. Volunteering is associated with higher life satisfaction, less depression and anxiety, better physical health, and more positive affect and less negative affect.

Antisocial Behavior

- Conduct disorder involves age-inappropriate actions and attitudes that violate family expectations, society's norms, and the personal or property rights of others. The disorder is more common in boys than in girls.
- Juvenile delinquency refers to actions taken by an adolescent in breaking the law or engaging in illegal behavior. In the Pittsburgh Youth Study, pathways to delinquency included conflict with authority, minor covert acts followed by property damage and more serious acts, and overt acts of minor aggression followed by fighting and violence. Associating with peers and friends who are delinquents, low parental monitoring, ineffective discipline, having an older sibling who is a delinquent, living in an urban, high-crime area, having low self-control, and having low intelligence are also linked with delinquency.

4 Values, Religion, Spirituality, and Meaning in Life

LG4 Characterize the development of values, religion, spirituality, and meaning in life.

Values

- Values are beliefs and attitudes about the way people think things should be. Over the last four decades, traditional-age college students have shown an increased interest in personal well-being and a decreased interest in the welfare of others.

Religion and Spirituality

- Distinctions have been made between the concepts of religion, religiousness, and spirituality. Many children, adolescents, and emerging adults show an interest in religion, and religious institutions strive to introduce them to religious beliefs.
- Cognitive changes in adolescence—such as increases in abstract, idealistic, and logical thinking—increase the likelihood that adolescents will seek a better understanding of religion and spirituality. As part of their search for identity, many adolescents and emerging adults begin to grapple with more complex aspects of religion. A downturn in religious interest among college students has occurred. When adolescents have a positive relationship with parents or are securely attached to them, they often adopt their parents' religious beliefs. Various aspects of religion are linked with positive outcomes in adolescent development.
- Religion is an important dimension of many American adults' lives as well as the lives of people around the world. Females tend to have a stronger interest in religion than males do. Although some people in certain religious sects try to avoid using medical treatment, individuals in the religious mainstream generally enjoy a positive or neutral link between religion and physical health. Religious interest often increases in late adulthood.

Meaning in Life

- Frankl argued that people need to face the finiteness of their life in order to understand life's meaning. Faced with the death of older relatives and less time to live themselves, middle-aged adults increasingly examine life's meaning.
- Baumeister described four main needs that guide how people try to make sense of their lives: (1) need for purpose, (2) need for values, (3) need for a sense of efficacy, and (4) need for self-worth.

section five

Social Contexts of Development

As children develop, their small world widens and they discover new contexts and people. As they grow through childhood, their parents still cradle their lives, but their lives also are shaped by successive choirs of peers and friends. Parents can give adolescents both roots and wings. When some adults become parents, they recognize for the first time how much effort their parents put into rearing them. In recent decades, increasing numbers of adults have chosen to get married later or not at all. As people age, they come to sense that the generations of living things pass in a short while, and, like runners, they pass on the torch of life. This section contains three chapters: "Families, Relationships, and Parenting," "Peers and the Sociocultural World," and "Schools, Achievement, and Work."

It is not enough for parents to understand children. They must also accord children the privilege of understanding them.

preview

Love and attachment are important aspects of family life. Beyond these emotional ties, what else goes on in families that influences development? And how do the choices that adults make about family life affect their development and the development of their children? These are some of the questions that we will consider in this chapter.

1 Family Processes

LG1 Describe some important family processes.

Reciprocal Socialization

Family as a System

Sociocultural and Historical Circumstances

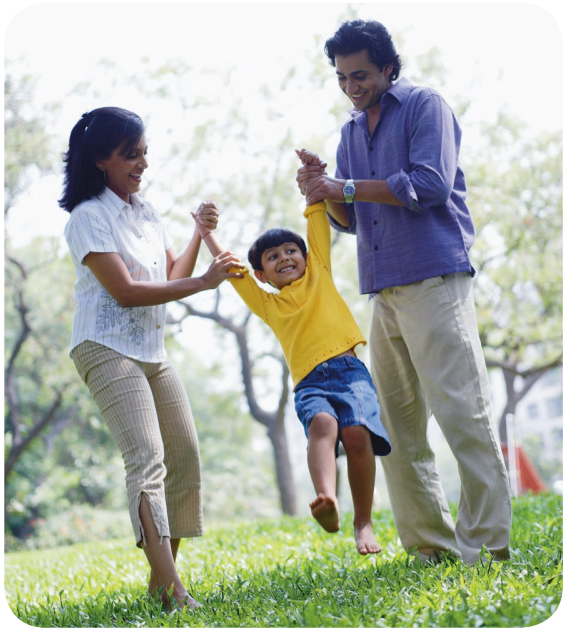
developmental **connection**

Environment

An important contribution of Bronfenbrenner's ecological theory is its focus on a range of social contexts that influence the child's development. Connect to "Introduction."

As we examine the family and other social contexts of development, consider Urie Bronfenbrenner's (1986, 2004; Bronfenbrenner & Morris, 2006) ecological theory, which we discussed in the "Introduction" chapter. Bronfenbrenner analyzes the social contexts of development in terms of five environmental systems:

- The *microsystem*, or the setting in which the individual lives, such as a family, the world of peers, schools, work, and so on
- The *mesosystem*, which consists of links between microsystems, such as the connection between family processes and peer relations
- The *exosystem*, which consists of influences from another setting (such as parents' work) that the individual does not experience directly
- The *macrosystem*, or the culture in which the individual lives, such as an ethnic group or a nation
- The *chronosystem*, or sociohistorical circumstances, such as increased numbers of working mothers, divorced parents, stepparent families, LGBTQ families, and multiethnic families in the United States in the last 30 to 40 years



Children socialize parents, just as parents socialize children.
Fuse/Getty Images

reciprocal socialization Socialization that is bidirectional in that children socialize parents just as parents socialize children.

RECIPROCAL SOCIALIZATION

Socialization between parents and children is not a one-way process. Parents do socialize children, but socialization in families is reciprocal (Hoyniak & others, 2021; Kochanska & Kim, 2020). **Reciprocal socialization** is socialization that is bidirectional; children socialize parents just as parents socialize children. These reciprocal interchanges and mutual influence processes are sometimes referred to as *transactional* (Martin & Donnellan, 2021; Nelemans & others, 2020).

For example, the interaction of parents and their infants is sometimes symbolized as a dance in which successive actions of the partners are closely coordinated (Provenzi & others, 2018). This coordinated dance can assume the form of synchrony—that is, each person's behavior depends on the partner's previous behavior. Or the interaction can be reciprocal in a precise sense, in which the actions of the partners can be matched, as when one partner imitates the other or when there is mutual smiling. An important example of early synchronized interaction is mutual gaze or eye contact. In one study, synchrony in parent-child relationships was positively related to children's social competence (Harrist, 1993). The types of behaviors involved in reciprocal socialization in infancy are temporally connected, mutually contingent behaviors such as one partner imitating the sound of another or the other partner responding with a vocalization to the baby's arm movements.

Another example of synchronization occurs in *scaffolding*, which means adjusting the level of guidance to fit the child's performance (Denervaud & others, 2020; Hoch & others, 2021). The parent responds to the child's behavior with scaffolding, which in turn affects the child's behavior. For example, in the game of peek-a-boo, parents initially cover their babies, then remove the covering, and finally register "surprise" at the babies' reappearance. As infants become more skilled at peek-a-boo, they gradually do some of the covering and uncovering. Parents try to time their actions in such a way that the infant takes turns with the parent. In addition to peek-a-boo, other caregiver games such as pat-a-cake and "so-big" exemplify scaffolding and turn-taking sequences.

Scaffolding can be used to support children's efforts at any age (Alexander & others, 2021; O'Neil & others, 2021). A recent study found that when adults used explicit scaffolding (encouragement and praise) with 13- and 14-month-old toddlers, the children were twice as likely to engage in helping behavior as were their counterparts who did not receive the scaffolding (Dahl & others, 2017). And a study of disadvantaged families revealed that an intervention designed to enhance parental scaffolding with infants was linked to improved cognitive skills when the children were 4 years old (Obradovic & others, 2016).

How does the game of peek-a-boo reflect the concept of scaffolding?
MIA Studio/Shutterstock

Increasingly, genetic and epigenetic factors are being studied to discover not only parental influences on children but also children's influence on parents (Clausing, Binder, & Non, 2021; Hoye & others, 2020). Recall that the *epigenetic view* emphasizes that development reflects an ongoing, bidirectional interchange between heredity and the environment (Monaco, 2021; Thaler & others, 2020). For example, harsh, hostile parenting is associated with children's negative behavior, such as defiance and oppositional behavior (Thompson & others, 2017). This likely reflects bidirectional influences rather than a unidirectional parenting effect. That is, the parents' harsh, hostile parenting and the children's defiant, oppositional behavior may mutually influence each other. In this bidirectional influence, the parents' and children's behavior may have genetic linkages as well as experiential connections.

developmental **connection**

Genetic Influences

Genotype-environment correlations and gene × environment interactions (G × E) reflect ways that the genetic heritage of children can be conceptualized and possibly influence parent-child relationships. Connect to "Biological Beginnings."

FAMILY AS A SYSTEM

As a social system, the family can be thought of as a constellation of subsystems defined in terms of generation, gender, and role (Seccombe, 2020). Divisions of labor among family members define particular subunits, and attachments define others. Each family member participates in several subsystems—some dyadic (involving two people) and some polyadic (involving more than two people) (McHale & Sirotkin, 2019). A parent and child represent one dyadic subsystem, two parents represent another dyadic subsystem; the parents and child(ren) represent one polyadic subsystem, a parent and two siblings another.

These subsystems interact with and influence each other (Williams, Sawyer, & Wahlstrom, 2020). Thus, as Figure 1 illustrates, the marital relationship, parenting, and infant/child behavior can have both direct and indirect effects on each other (Belsky, 1981). The link between marital relationships and parenting has recently received increased attention (Kuo & Johnson, 2021). For example, marital conflict might reduce the efficiency of parenting, in which case marital conflict would indirectly affect the child's behavior. In a recent study, destructive marital conflict was linked to lower levels of coparenting alliance (Kopystynska, Barnett, & Curran, 2020).

Researchers have found that promoting marital satisfaction often leads to good parenting in families with two parents who are married to each other. The marital relationship is an important support for parenting (Davies & others, 2021). When parents report more intimacy and better communication in their marriage, they are more affectionate with their children (Grych, 2002). Thus, marriage-enhancement programs may end up improving parenting and helping children (Nunes & others, 2020). Programs that focus on parenting skills might also benefit from including attention to the participants' marriages.

Family

Many families who have immigrated into the United States in recent decades, such as Mexican Americans and Asian Americans, come from collectivist cultures in which family obligations are strong. Connect to "Peers and the Sociocultural World."

developmental **connection**

Screen Time

Recent research indicates that children's and adolescents' media use/screen time have increased dramatically in the last decade. Connect to "Peers and the Sociocultural World."

Two important changes in families are increased mobility of families and increased media use. *What are some other changes?*
(*Top*): Kali9/E+/Getty Images; (*bottom*): JGI/Jamie Grill/Getty Images

SOCIOCULTURAL AND HISTORICAL INFLUENCES

Family development does not occur in a social vacuum. Important sociocultural and historical influences affect family processes, which reflect Bronfenbrenner's concepts of the macrosystem and chronosystem (Bronfenbrenner & Morris, 2006). Great upheavals such as war, famine, or mass immigration as well as subtle transitions in ways of life may stimulate changes in families (Masten, 2021a, b). One example is the effect on U.S. families of the Great Depression of the 1930s. During its height, the Depression produced economic deprivation, adult discontent, and dissatisfaction with living conditions. It also increased marital conflict, inconsistent child rearing, and unhealthy lifestyles—heavy drinking, demoralized attitudes, and health problems—especially in fathers (Elder, 1980).

A major change in families during the last several decades has been the dramatic increase in the immigration of Latinx and Asian families into the United States (Gollnick & Chinn, 2021). These families often experience stressors uncommon to or less prominent among long-time residents, such as language barriers, dislocations and separations from support networks, the dual struggle to preserve identity and to acculturate, and changes in socioeconomic status (Amirkhan & Velasco, 2021; Dandy & Drake, 2020). We discuss ethnic variations in families more extensively in the chapter on "Peers and the Sociocultural World."

Subtle changes in a culture have significant influences on the family (Mayo & Wadsworth, 2020). Such changes include the increased longevity of older adults; movement from rural communities to urban and suburban areas; widespread use of television, computers, the Internet, and digitally mediated communication; and a general dissatisfaction and restlessness (Hay, Sageman, & Allan, 2021; Maloy & others, 2021).

Early in the twentieth century, middle-aged and older adults were often closely linked to the family (Mead, 1978). Today, older parents may have lost some of their socializing role in the family as many of their children moved considerable distances away. However, as we see later in the chapter, in the twenty-first century an increasing number of grandparents are raising their grandchildren.

In the twentieth century, many families moved from farms and small towns to urban and suburban settings (Mead, 1978). In the small towns and farms, individuals were surrounded by lifelong neighbors, relatives, and friends. Today, neighborhood and extended-family support systems are not nearly as prevalent. Families now move all over the country, often uprooting children from a school and peer group they have known for a considerable length of time. And it is not unusual for this type of move to occur several times during childhood as one or both parents are transferred from job to job.

Further, an increasing number of children are growing up in transnational families who move back and forth between countries, such as between the United States and Mexico or between the United States and China (Rios Casas & others, 2020). In some cases, these children are left behind in their home country or are sent back to be raised by grandparents during their early childhood years. Such children might benefit from economic support but suffer emotionally from prolonged separation from their parents.

Media use and screen time also play a major role in the changing family (Hayba & others, 2020). Many children who watch television, use computers, or communicate with friends on mobile devices such as smartphones find that their parents are too busy working to share this experience with them (Maloy & others, 2021). Children increasingly experience a world in which their parents are not participants. Instead of interacting in neighborhood peer groups, children come home after school and watch television or log on to a computer. Recent research with adolescents indicated that light use of digital media (less than 1 hour a day) was associated with much higher psychological well-being than heavy use of digital media (5+ hours a day) (Twenge & Campbell, 2019). Among the historical changes related to computers, consider the dramatic increase in young people's participation on Internet social networking sites (Alonzo & others, 2021; Kross & others, 2021). In a recent study, social media use of more than 2 hours per day was linked to lower academic achievement in both middle and high school (Sampasa-Kanyinga, Chaput, & Hamilton, 2019).

Another change in families has been an increase in general dissatisfaction and restlessness (Mead, 1978). The result of such restlessness and the tendency to divorce and remarry has been a hodgepodge of family structures, with far greater numbers of divorced and remarried families than ever before. Later in the chapter, we will discuss in greater detail these aspects of the changing social world of the child and the family.

Reflect *Your Own Personal Journey of Life*

- Reflect for several moments on your own family as you were growing up, and give some examples of the family processes discussed in this section as you experienced them in your own family.

2 The Diversity of Adult Relationships and Families

LG2 Discuss the diversity of adult relationships and families and how they influence people's lives.

Single Adults | Cohabiting Adults | Married Adults | Divorced Adults | Remarried Adults | LGBTQ Adults

A striking social change in recent decades has been the decreased stigma attached to individuals who do not maintain what were long considered conventional families. Adults today choose among many different relationships and form many types of families (Williams, Sawyer, & Wahlstrom, 2020). They may live alone, cohabit, marry, or divorce, and their partner may be same-gender or different-gender (Seccombe, 2020).

In his book *The Marriage-Go-Round*, sociologist Andrew Cherlin (2009) concluded that the United States has more marriages and remarriages, more divorces, and more short-term cohabiting (living together) relationships than most countries. Combined, these lifestyles create more turnover and movement in and out of relationships in the United States than in virtually any other country. For example, in a recent cross-national comparison of the United States and seven European countries, the United States was most likely to be characterized by a high degree of union instability in marriage and cohabitation (Musick & Michelmore, 2018). Let's explore these varying relationship lifestyles.

SINGLE ADULTS

Recent decades have seen increasing percentages of single adults. In 2019, 35 percent of men and 30 percent of women had never been married, compared with 30 percent of men and 23 percent of women in 1990 (U.S. Census Bureau, 2019). Also, African American adults (47 percent) are much more likely to be single than non-Latinx White (28 percent) and Latinx adults (27 percent) (Brown, 2020). Single-person households increased from 7 million in 1960 to 36 million in 2019.

The increasing number of single adults is influenced by rising rates of cohabitation and a trend toward postponing marriage. However, the United States actually has a lower percentage of single adults than many other countries, such as Great Britain, Germany, and Japan. Moreover, the fastest growth in individuals adopting a single adult lifestyle is occurring in rapidly developing countries such as China, India, and Brazil (Klinenberg, 2012, 2013).

Advantages of being single include having time to make decisions about one's life course, time to develop personal resources to meet goals, freedom to make autonomous decisions and pursue one's own schedule and interests, opportunities to explore new places and do new things, and privacy. Compared with married adults, single adults are more likely to spend time with friends and neighbors, go out to restaurants, and attend art classes and lectures (Klinenberg, 2012, 2013). Once adults reach the age of 30, they may face increasing pressure to settle

down and get married. This is when many single adults make a conscious decision to marry or to remain single.

Given all of the technologies that are now available, it is probably easier to meet someone today than ever before. However, many individuals are looking for the perfect soul mate and that person is hard to find. And with all of the dating websites available, once someone finds a flaw in the person they are dating, it is not difficult to quickly search for and find someone else to date. Also, in contrast with the negative stereotyping of singles in earlier decades, it has become much more acceptable to pursue a single lifestyle.

In a national survey of more than 35,000 U.S. single adults, *fast sex and slow love* characterized their responses (Fisher & Garcia, 2019). In terms of fast sex, 66 percent of U.S. singles reported having had a one-night stand, 34 percent had sex with someone before a first date, and 54 percent had experienced an uncommitted, secretive friends-with-benefits relationship (Fisher & Garcia, 2019). However, in terms of slow love, today's singles are taking far longer than previous generations to commit to love and marriage, wanting to know everything they can about a potential partner before they invest time, effort, and money to make a formal commitment to him or her (Fisher & Garcia, 2019). And even though uncommitted sexual experiences have become much more common, today's singles still have a strong interest in finding romantic love. In a recent poll, more than 54 percent of U.S. singles said they believe in "love at first sight," 86 percent reported that they want to find a committed partner they can live with forever, and 89 percent responded that they believe it is possible to remain married to the same person for the rest of one's life (Fisher & Garcia, 2019).

Approximately 8 percent of all individuals in the United States who reach the age of 65 have never been married. Contrary to the popular stereotype, older adults who have never been married seem to have the least difficulty coping with loneliness in old age. Many have discovered long ago how to live autonomously and how to be self-reliant.

COHABITING ADULTS

Cohabitation refers to living together in a sexual relationship without being married. Cohabitation has undergone considerable changes in recent years (Sassler & Lichter, 2020). For example, there has been a dramatic increase in the number of cohabiting U.S. couples (Manning, 2020). In a national poll, the number of cohabiting adults increased 29 percent from 2007 to 2016, reaching a total of 18 million adults in a cohabiting relationship (U.S. Census Bureau, 2016). In 2018, 15 percent of U.S. adults 25 to 34 and 9 percent who were 18 to 24 years old were cohabiting (U.S. Census Bureau, 2019). At lower SES levels, couples are more likely to cohabit and give birth prior to marriage and less likely to marry at all (Karney, 2021). Engaging in serial cohabitation—exiting one cohabitation and then entering another—has increased in the last decade in the United States (Eickmeyer & Manning, 2018). Cohabitation rates are even higher in some countries, especially in Scandinavian countries (Smock & Schwartz, 2020). Cohabitation is increasing in China and Taiwan but still rare in Japan and South Korea. Also, a recent study indicated that early transitioning into a stepfamily home, especially for women, was linked to earlier entry into cohabitation (Johnston, Cavanagh, & Crosnoe, 2020).

What are some potential advantages and disadvantages of cohabitation?
Chris Ryan/OJO Images/Getty Images

cohabitation Living together in a sexual relationship without being married.

In the United States, cohabitation is often perceived as a precursor to marriage, while in Europe—especially in Scandinavian countries—it is more frequently perceived as an ongoing lifestyle (Sassler & Lichter, 2020). In the United States, cohabiting arrangements tend to be short-lived, with one-third lasting less than a year (Hyde & DeLamater, 2020). Fewer than 1 out of 10 last five years. Of course, it is easier to dissolve a cohabitation relationship than to divorce.

Couples who cohabit face certain problems (Johnson & others, 2020). Disapproval by parents and other family members can place emotional strain on the cohabiting couple. Some cohabiting couples have difficulty purchasing property jointly. Legal rights regarding the dissolution of the relationship are less certain than in a divorce. Researchers have found that following the transition from dating to cohabitation, relationships are characterized by more commitment, lower satisfaction, more negative communication, and more physical aggression than when dating (noncohabiting) (Rhoades, Stanley, & Markman, 2012). Other recent research confirms that cohabitation is a risk factor for intimate partner violence in emerging adults (Manning, Longmore, & Gordano, 2018). And in a recent national survey, married adults had higher rates of relationship satisfaction than unmarried adults who cohabit (Horowitz, Graf, & Livingston, 2019).

Cohabitation and Marital Stability/Happiness If a couple chooses to live together before they marry, does cohabiting help or harm their chances of later having a stable and happy marriage? The majority of studies have found lower rates of marital satisfaction and higher rates of divorce in couples who lived together before getting married (Blumberg, Vahratian, & Blumberg, 2014). However, research indicates that the link between marital cohabitation and marital instability in first marriages has weakened in recent cohorts (Sassler & Lichter, 2020).

What might explain the finding that cohabiting is linked with divorce more than not cohabiting? The most frequently given explanation is that the less traditional lifestyle of cohabitation may attract less conventional individuals who are not strong believers in marriage in the first place. An alternative explanation is that the experience of cohabiting changes people's attitudes and habits in ways that increase their likelihood of divorce.

Research has provided clarification of cohabitation outcomes. One meta-analysis found that the link between cohabitation and marital instability did not hold up when only cohabitation with the eventual marital partner was examined, indicating that these cohabitors may attach more long-term positive meaning to living together (Jose, O'Leary, & Moyer, 2010). One study also found that the marriages of couples who were cohabiting but not engaged were less likely to survive to the 10- to 15-year mark than the marriages of their counterparts who were engaged when they cohabited (Copen, Daniels, & Mosher, 2013). Also, one analysis indicated that cohabiting does not have a negative effect on marriage if the couple did not have any previous live-in lovers and did not have children prior to the marriage (Cherlin, 2009). And another study concluded that the risk of marital dissolution between cohabitors and those who married without previously cohabiting was much smaller when they cohabited in their mid-twenties and later (Kuperberg, 2014).

Cohabiting Older Adults An increasing number of individuals 50 years of age and older cohabit (Smock & Schwartz, 2020). Cohabitation levels more than doubled for middle-aged and older adult men from 1990 (1.5 percent) to 2015 (3.8 percent) and also increased for middle-aged and older adult women in the same time frame from less than 1 percent to 2.6 percent (Brown & Wright, 2017). These percentages are expected to continue increasing.

In many cases, cohabiting among older couples is more for companionship than for love. In other cases—for example, when one partner faces the potential for expensive long-term care—a couple may decide to maintain their assets separately and thus not marry. One study found that older adults who cohabited had a more positive, stable relationship than younger adults who cohabited, although older adults who cohabited were less likely to make plans to marry their partner (King & Scott, 2005). In one study, cohabiting older adults were less likely to receive partner care than married older adults (Noel-Miller, 2011).

MARRIED ADULTS

Until about 1930, stable marriage was widely accepted as a hallmark of adult development. Almost a century later, however, personal fulfillment both inside and outside of marriage has emerged as a goal that competes with marital stability. The changing norm of gender equality in marriage and increasingly high expectations regarding what a successful marriage should look like have produced marital relationships that are more fragile and intense than marriages earlier in the twentieth century (Cherlin, 2020).

> When two people are under the influence of the most violent, most insane, most delusive, and most transient of passions, they are required to swear that they will remain in that excited, abnormal, and exhausting condition continuously until death do them part.
>
> —George Bernard Shaw
> *Irish Playwright, 20th Century*

Marital Trends In 2019, 48.2 percent of individuals 18 and older in the United States were married, down from 72 percent in 1960 (U.S. Census Bureau, 2019). Also, in 2019, the U.S. average age for a first marriage had climbed to 30 years for men and 28 years for women, higher than at any other point in history (U.S. Census Bureau, 2019). In 1960, the average age for a first marriage in the United States was 23 years for men and 20 years for women. Also, as indicated earlier, a higher percentage of U.S. adults never marry—in 2019, a record percentage (35 percent of men, 30 percent of women) of adults had never married (U.S. Census Bureau, 2020). In addition, the increasing cohabitation rate in the United States has contributed to the lower percentage of adults who are married.

Marriage rates vary according to ethnicity in the United States. In 2018, 63 percent of Asian American adults were married, followed by 57 percent on non-Latinx Whites, 48 percent of Latinxs, and 33 percent of African Americans (U.S. Census Bureau, 2019). Marriage rates

between individuals from different ethnic groups have increased dramatically. In 1967, 3 percent of newlyweds and 3 percent of all married people were from different ethnic backgrounds; in 2015 those figures had risen to 17 percent of newlyweds and 10 percent of all married persons (Livingston & Brown, 2017). The largest percentage increase in intermarriage in recent years has occurred for African Americans (from 5 percent in 1980 to 15 percent in 2015) and non-Latinx Whites (from 4 percent in 1980 to 11 percent in 2015).

The age at which individuals get married is increasing, not just in the United States but also in many other countries. Also, in recent analyses, age at first marriage in most developed countries is later than it is in the United States (OECD, 2016). For example, in a comparison of 39 developed countries, average age at first marriage now is older in Sweden (34 for women and 36 for men) than in the other 38 countries. Earliest average age at first marriage in these developed countries is occurring in Turkey (25 for women and 27 for men).

Although marriage rates are declining and the average age for a first marriage is going up, research with emerging and young adults indicates that they view marriage as a very important life pursuit. Indeed, in one study young adults predicted that marriage would be more important in their life than parenting, careers, or leisure activities (Willoughby, Hall, & Goff, 2015). In a recent book, *The Marriage Paradox* (Willoughby & James, 2017), the authors concluded that the importance of marriage to emerging and young adults may be what is encouraging them to first build a better career and financial foundation to increase the likelihood that their marriage will be successful later. From this perspective, emerging and young adults may not be abandoning marriage because they don't like it or are uninterested in it, but rather postponing it because they want to position themselves in the best possible way for developing a healthy marital relationship.

A recent survey explored why individuals get married (Geiger & Livingston, 2019). At the top of the list was love (88 percent), followed by making a lifelong commitment (81 percent), companionship (76 percent), and having children (49 percent). Another study explored what U.S. never-married men and women are looking for in a potential spouse (Wang, 2014). Following are the percentages who reported that various factors would be very important to them:

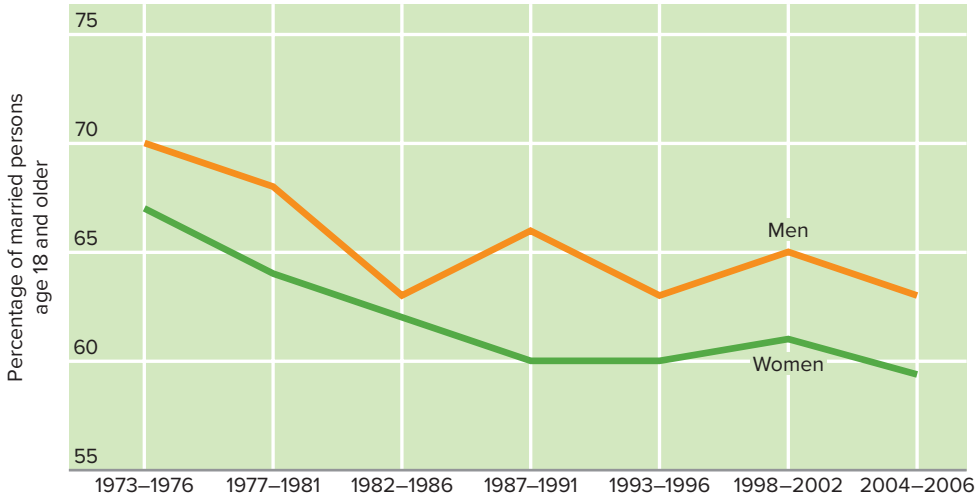
Factor	Men	Women
Similar ideas about having and raising children	62	70
A steady job	46	78
At least as much education	26	28
Same racial or ethnic background	7	10

Thus, in this study, never-married men said that the most important factor for a potential spouse was similar ideas about having and raising children, but never-married women placed greater importance on having a partner with a steady job.

How happy are people who do marry? As indicated in Figure 2, the percentage of married individuals in the United States who said their marriages were "very happy" declined from the 1970s through the early 1990s, increased around the turn of the century, and then declined again (Popenoe, 2009). Notice in Figure 2 that married men consistently report being happier than married women.

FIGURE **2**

PERCENTAGE OF MARRIED PERSONS AGE 18 AND OLDER WITH "VERY HAPPY" MARRIAGES.



Also, in a recent study across a number of countries and religions, men reported higher marital satisfaction than women (Sorokowski, Kowal, & Sorkowska, 2019). In this study, levels of marital satisfaction were similar for Muslims, Christians, and atheists. And a study of 502 newlyweds found that nearly all couples had optimistic forecasts of how their marriage would change over the next four years (Lavner & Bradbury, 2013). Despite their optimistic forecasts, their marital satisfaction declined across this time frame. Wives with the most optimistic forecasts showed the steepest declines in marital satisfaction.

The Benefits of a Good Marriage Are there any benefits to having a good marriage? There are several (Lavner & Bradbury, 2019). Individuals who are happily married live longer, healthier lives than individuals who are divorced or unhappily married (Seccombe, 2020). In a research review, it was concluded that the experience of divorce or separation confers risk for poor health outcomes, including a 23 percent higher mortality rate (Sbarra, 2015). A survey of U.S. adults age 50 and older also revealed that being married for a lower proportion of adult life was linked to an increased likelihood of dying at an earlier age (Henretta, 2010). Further, an unhappy marriage can shorten a person's life by an average of four years (Gove, Style, & Hughes, 1990).

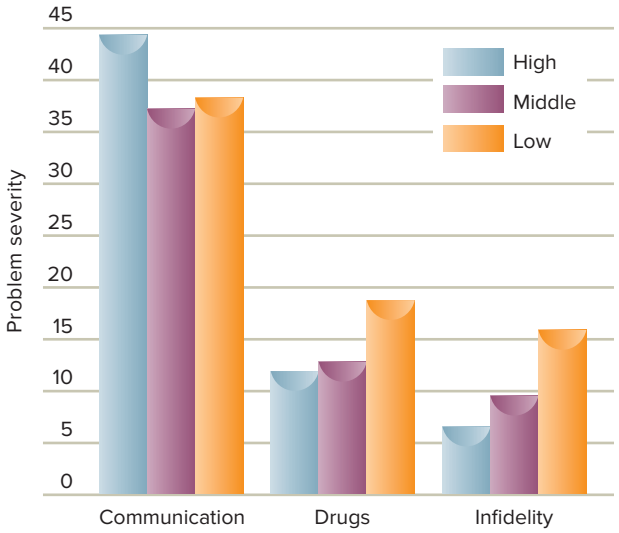


FIGURE 3
SEVERITY OF SPECIFIC RELATIONSHIP PROBLEMS IN LOW-, MIDDLE-, AND HIGH-INCOME HOUSEHOLDS.

Social Contexts Contexts within a culture and across cultures are powerful influences on marriage (Salinger & others, 2021). A U.S. study found that although poor communication was rated as a relatively severe problem regardless of household income, it was rated as most severe in high-income households (Karney, Garvin, & Thomas, 2003) (see Figure 3). By contrast, drugs and infidelity were rated as more severe problems in low-income households than in middle- or high-income households.

Many aspects of marriage vary across cultures. For example, as part of China's efforts to control population growth, a 1981 law set the minimum age for marriage at 22 years for men and 20 for women, and that law was still in effect in 2021. Further, in many parts of the world, such as India, arranged marriages are common.

The traits that people look for in a marriage partner vary around the world. In one large-scale study of 9,474 adults from 37 cultures on six continents and five islands, people varied most regarding how much they valued chastity—desiring a marital partner with no previous experience in sexual intercourse (Buss & others, 1990). Chastity was the most important characteristic in selecting a marital partner in China, India, Indonesia, Iran, Taiwan, and the Palestinian Arab culture. Adults from Ireland and Japan placed moderate importance on chastity. In contrast, adults in Sweden, Finland, Norway, the Netherlands, and Germany generally said that chastity was not important in selecting a marital partner.

Religion plays an important role in marital preferences in many cultures (Fieder, Schahbasi, & Huber, 2020). For example, Islam stresses the honor of men and the purity of women. It also emphasizes the woman's role in childbearing, child rearing, educating children, and instilling the Islamic faith in children.

(*a*)

(*b*)

(*c*)

(*a*) In Scandinavian countries, cohabitation is popular; only a small percentage of 20- to 24-year-olds are married. (*b*) Islam stresses male honor and female purity. (*c*) Japanese young adults live at home longer with their parents before marrying than young adults in most other countries.

John Gottman has conducted extensive research on what makes marriages work.
Courtesy of The Gottman Institute, www.gottman.com

Unlike most approaches to helping couples, mine is based on knowing what makes marriages succeed rather than fail.

—JOHN GOTTMAN
Contemporary Psychologist, University of Washington

What Makes Marriages Work John Gottman (1994, 2021a) has been studying married couples' lives since the early 1970s. He uses many methods to analyze what makes marriages work. Gottman interviews couples about the history of their marriage, their philosophy about marriage, and how they view their parents' marriages. He videotapes spouses talking with each other about how their day went and evaluates what they say about the good and bad times of their marriages. Gottman also uses physiological measures to track their heart rate, blood flow, blood pressure, and immune functioning moment by moment. He checks back with the couples every year to see how their marriage is faring. Gottman's research represents the most extensive assessment of marital relationships available. Currently he and his colleagues are following 700 couples in seven studies.

In his research, Gottman has identified the following factors as important predictors of success in marriage (Gottman & Silver, 1999):

- *Establishing love maps*. Individuals in successful marriages have personal insights and detailed maps of each other's life and world. They aren't psychological strangers. In good marriages, partners are willing to share their feelings with each other. They use these "love maps" to express not only their understanding of each other but also their fondness and admiration.
- *Nurturing fondness and admiration*. In successful marriages, partners sing each other's praises. More than 90 percent of the time, when couples put a positive spin on their marriage's history, their marriage is likely to have a positive future.
- *Turning toward each other instead of away*. In good marriages, spouses are adept at turning toward each other regularly. They see each other as friends. This friendship doesn't keep arguments from occurring, but it can prevent differences from overwhelming the relationship. In these good marriages, spouses respect each other and appreciate each other's points of view despite disagreements.
- *Letting your partner influence you*. Bad marriages often involve one spouse who is unwilling to share power with the other. Although power-mongering is more common in husbands, some wives also show this trait. A willingness to share power and to respect the other person's point of view is a prerequisite to compromising. In one study, researchers found that equality in decision making was one of the main factors that predicted positive marriage quality (Amato & others, 2007).
- *Overcoming gridlock*. One partner wants the other to attend church, but the other is an atheist. One partner is a homebody, but the other wants to go out and socialize a lot. Such problems often produce gridlock. Gottman stresses that the key to ending gridlock is not to solve the problem but to move from gridlock to dialogue and to be patient.
- *Creating shared meaning*. The easier it is for partners to speak candidly and respectfully with each other, the more likely it is that they will create shared meaning in their marriage. This also includes sharing goals with one's spouse and working together to achieve each other's goals.

What makes marriages work? What are the benefits of having a good marriage?
Image Source/Alamy Stock Photo

In addition to Gottman's view, other experts on marriage argue that such factors as forgiveness and commitment are important aspects of a successful marriage (Karney & Bradbury, 2020; Lavner & Bradbury, 2019). These factors function as self-repair processes in healthy relationships. For example, spouses may have a heated argument that has the potential to harm their relationship. After calming down, they may forgive each other and repair the damage. A couple's personality traits also may influence how satisfied individuals are with their marriage. For example, a recent study found that couples high in neuroticism were less satisfied with their marriage than couples high in conscientiousness (Sayehmiri & others, 2020).

Premarital Education Premarital education occurs in a group and focuses on relationship advice. Might premarital education improve the quality of a marriage and possibly reduce the chances that the marriage will end in divorce? Researchers have found that it can (Markman, Halford, & Hawkins, 2019). For example, a survey of more than 3,000 adults revealed that premarital education was linked to a higher level of marital satisfaction

Trend	Proposal
Individualism and Commitment Ambivalence	Premarital education needs to guide couples in transitioning from "me" to "we" and developing a strong commitment to their marriage.
Meaning of and Attitudes about Marriage	Premarital education should help individuals clarify for themselves and with their partner the meaning of marriage and their attitudes about it.
Premarital Relationship History and Experiences	Premarital education needs to focus on the complexities and challenges of marriage that many couples will experience as a result of considerable premarital experience, cohabitation, and premarital childbearing.
Effects of Media	Premarital education should help couples explore the effects of media use on marital attitudes and behavior.

FIGURE **4**

TRENDS AND PROPOSALS FOR IMPROVING PREMARITAL EDUCATION IN THE NEXT GENERATION.

and commitment to a spouse, a lower level of destructive marital conflict, and a 31 percent lower likelihood of divorce (Stanley & others, 2006). It is recommended that premarital education begin approximately six months to a year before the wedding.

A recent analysis and review examined research on contemporary trends that influence the next generation's ability to form and sustain a positive marriage (Clyde, Hawkins, & Willoughby, 2020). In light of these trends, the authors of the research review offered four proposals to improve the effectiveness of premarital education. Figure 4 describes these trends and proposals.

Marriage in Middle and Late Adulthood What is marriage like for middle-aged adults? How does marriage change in late adulthood?

Middle Adulthood Some marriages that were difficult and rocky during early adulthood improve during middle adulthood (Seccombe, 2020). Although the partners may have lived through a great deal of turmoil, they eventually discover a deep and solid foundation on which to anchor their relationship. In middle adulthood, the partners may have fewer financial worries, less housework and chores, and more time to spend with each other. Partners who engage in mutual activities usually view their marriage more positively. Also, one study found that middle-aged married individuals had a lower likelihood of work-related health limitations (Lo, Cheng, & Simpson, 2016). However, marital conflict can be problematic in middle age. In a longitudinal study, hostile marital interactions increased couples' psychological distress, health-risk behaviors, and body mass index (BMI) in early middle age, which in turn were linked to an increased vulnerability for physical illness in later life (Lee & others, 2021).

Might relationship skills in emerging adulthood predict marital adjustment in middle age? A longitudinal study revealed that individuals with higher levels of emotional intimacy skills in their early twenties were more likely to have well-adjusted marriages in middle age than their counterparts with lower levels of intimacy skills in their twenties (Boden, Fischer, & Niehuis, 2010).

Late Adulthood In 2019, 57 percent of U.S. adults over 65 years of age were married (Administration on Aging, 2020). Older men (69 percent) were far more likely to be married than older women (47 percent). In 2019, 31 percent of U.S. adults over 65 years of age were widowed (Administration on Aging, 2020). There were more than three times as many widows as widowers.

Individuals who are in a marriage or a partnership in late adulthood are usually happier, are less distressed, and live longer than those who are single (Roberto & Weaver, 2019). One study found that older adults were more satisfied with their marriages than were young and middle-aged adults (Bookwala & Jacobs, 2004). Also, a longitudinal study of adults 75 years of age and older revealed that individuals who were married were less likely to die during a seven-year time span (Rasulo, Christensen, & Tomassini, 2005). And a recent study of married

developmental **connection**

Widows

Women who are 65 years of age and older are far more likely to be widowed than to be divorced. Connect to "Death, Dying, and Grieving."

What are some adaptations that many married older adults need to make?
Image Source

Grow old along with me!
The best is yet to be,
The last of life,
For which the first was made.

—Robert Browning
English Poet, 19th Century

Mexican older adults found that experiencing more spousal support was associated with less loneliness, while experiencing spousal strain was linked to more loneliness three years later (Saenz, 2021).

In late adulthood, married individuals are likely to find themselves having to care for a sick partner with a limiting health condition (Blieszner & Ogletree, 2018). The stress of caring for a spouse who has a chronic disease can place demands on intimacy (Polenick & DePasquale, 2019).

DIVORCED ADULTS

During the mid-twentieth century divorce reached epidemic proportions in the United States. However, the divorce rate declined in recent decades, peaking at 5.1 divorces per 1,000 people in 1981 and then declining to 2.9 divorces per 1,000 people in 2018 (U.S. Census Bureau, 2019). The 2018 divorce rate of 2.9 compares with a marriage rate of 6.5 per 1,000 people in 2018.

Although the divorce rate has dropped, the United States still has one of the highest divorce rates in the world. In a recent comparison of 39 developed countries, Russia had the highest divorce rate by far (4.6 divorces per 1,000 people), Chile the lowest (0.2 divorces per 1,000 people) (OECD, 2019). In the United States, nearly half of first marriages will break up within 20 years (Copen, Daniels, & Mosher, 2013).

As with marriage rates, ethnic variations characterize divorce rates (American Community Survey, 2014). Asian Americans are least likely to be divorced, with 18 percent of Asian American women and 16 percent of men experiencing at least one divorce in their lifetime. For Latinxs, 30 percent of women and 27 percent of men become divorced in their lifetime. For non-Latinx Whites, 38 percent of women and 36 percent of women become divorced in their lifetime. And for African Americans, 42 percent of women and men experience divorce in their lifetime.

Individuals in some other groups also have a higher incidence of divorce than others do (Smock & Schwartz, 2020). Youthful marriage, low educational level, low income, not having a religious affiliation, having parents who are divorced, and having a baby before marriage are associated with increased rates of divorce (Hoelter, 2009). And characteristics of one's partner that increase the likelihood of divorce include alcoholism, psychological problems, domestic violence, infidelity, and inadequate division of household labor (Affleck, Carmichael, & Whitley, 2018).

Certain personality traits also have been found to predict divorce. In a study that focused on the Big Five personality factors, low levels of agreeableness and conscientiousness, as well as high levels of neuroticism and openness to experience, were linked to daily experiences that over time negatively impacted relationship quality and eventually led to a marital breakup (Solomon & Jackson, 2014).

Earlier, we indicated that researchers have not been able to pin down a specific age that is the best time to marry in order to reduce the likelihood of divorce. However, if a divorce is going to occur, it usually takes place between the fifth and tenth years of marriage (National Center for Health Statistics, 2000) (see Figure 5). For example, one study found that divorce peaked in Finland at approximately 5 to 7 years after a marriage, and then the rate of divorce gradually declined (Kulu, 2014). This timing may reflect an effort by partners in troubled marriages to stay in the marriage and try to work things out. If after several years these efforts have not improved the relationship, they may then seek a divorce.

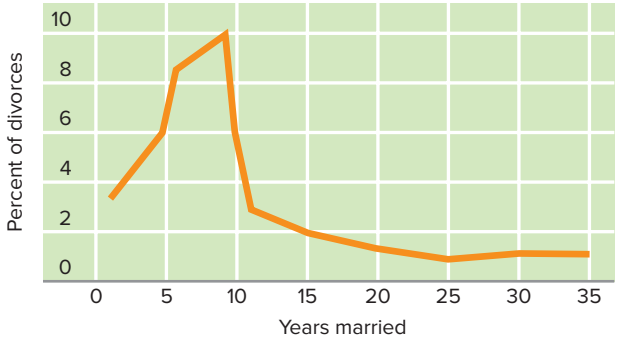

FIGURE **5**

THE DIVORCE RATE IN RELATION TO NUMBER OF YEARS MARRIED. Shown here is the percentage of divorces as a function of how long couples have been married. Notice that most divorces occur in the early years of marriage, peaking in the fifth to tenth years of marriage.

What causes people to get divorced? A study in Great Britain found no differences in the causes of breakdowns in marriage and cohabitation (Gravningen & others, 2017). In this study, the following percentages cited these reasons: "grew apart" (men: 39 percent, women: 36 percent); "arguments" (men: 27 percent, women: 30 percent); "unfaithfulness/adultery" (men: 18 percent, women: 24 percent); "lack of respect, appreciation" (men: 17 percent, women: 25 percent); and "domestic violence" (men: 4 percent, women: 16 percent).

Even those adults who initiated their divorce go through challenges after a marriage dissolves (Tamers & others, 2014). Both divorced women and divorced men complain of loneliness, diminished self-esteem, anxiety about the unknowns in their lives, and difficulty forming satisfactory new intimate relationships.

The stress of separation and divorce places both men and women at risk for psychological and physical difficulties (Moons & others, 2021). Separated and divorced women and men have higher rates of psychiatric disorders, admission to psychiatric hospitals, clinical depression, alcoholism, and psychosomatic problems such as sleep disorders than do married adults (Axinn & others, 2020).

There are gender differences in the process and outcomes of divorce (Leopold, 2018). Women are more likely to sense that something is wrong with the marriage and to seek a divorce than are men. Women also show better emotional adjustment and are more likely to perceive divorce as offering a "second chance" to increase their happiness, improve their social lives, and seek better work opportunities. However, divorce typically has a more negative economic impact on women than on men.

What are some strategies for coping with divorce?
Image Source/Getty Images

Coping with Divorce Psychologically, one of the most common characteristics of divorced adults is difficulty trusting someone else in a romantic relationship. Following a divorce, though, people's lives can take diverse turns (Raley & Sweeney, 2020). Strategies to produce positive outcomes for divorced adults include the following (Hetherington & Kelly, 2002):

- Think of divorce as a chance to grow personally and to develop more positive relationships.
- Make decisions carefully. The consequences of your decisions regarding work, lovers, and children may last a lifetime.
- Focus more on the future than the past. Think about what is most important to help you go forward in your life, and then set some challenging goals and plan how to reach them.
- Use your strengths and resources to cope with difficulties.
- Don't expect to be successful and happy in everything you do. "The road to a more satisfying life is bumpy and will have many detours" (p. 109).
- Remember that "you are never trapped by one pathway. Most of those who were categorized as defeated immediately after divorce gradually moved on to a better life, but moving onward usually requires some effort" (p. 109).

Divorced Middle-Aged Adults What trends characterize divorce in U.S. middle-aged adults? In a recent analysis that compared divorce rates for different age groups in 1990 to 2015, the divorce rate decreased for young adults but increased for middle-aged and older adults (Stepler, 2017):

25 to 39 years	40 to 49 years	50+ years
−21 percent	+14 percent	+109 percent

The recent increase in divorce among middle-aged adults has led to divorce in middle adulthood being labeled "gray divorce" when it occurs after 50 years of age (Tosi & van den Broek, 2020).

What accounts for increased rates of divorce among middle-aged and older adults? One explanation is the changing status of women, who initiate approximately 60 percent of the divorces after 40 years of age. Compared with earlier decades, divorce has less stigma for women today and they are more likely to leave an unhappy marriage. Also compared with earlier decades, more women are employed and are less dependent on their husband's income. Another explanation involves the increase in remarriages, in which the divorce rate is 2½ times as high as it is for those in first marriages.

A survey by AARP (2004) of more than 1 million 40- to 79-year-olds who were divorced at least once in their forties, fifties, or sixties found that staying married because of their children was by far the main reason many people took so long to become divorced. Despite the worry and stress involved in going through the divorce process, three out of four of the divorcees said they had made the right decision to dissolve their marriage and reported a positive outlook on life. Sixty-six percent of the divorced women said they had initiated the divorce, compared with only 41 percent of the divorced men. The divorced women were much more afraid of having financial problems (44 percent) than the divorced men were (11 percent). Following are the main reasons these middle-aged and older adults cited for their divorce:

What are some characteristics of divorce in middle-aged adults?
Denkou Images/Alamy Stock Photo

Main Causes of Divorce for Women

- Verbal, physical, or emotional abuse (23 percent)
- Alcohol or drug abuse (18 percent)
- Cheating (17 percent)

Main Causes of Divorce for Men

- No obvious problems; just fell out of love (17 percent)
- Cheating (14 percent)
- Different values, lifestyles (14 percent)

In recent research on the antecedents of "gray divorce," factors traditionally associated with divorce in young adults also were reflected in divorces of adults 50 years and older (Raley & Sweeney, 2020). Divorce was more likely to occur for older adults when they had been married fewer years, their marriage was of lower quality (less marital satisfaction, for example), they did not own a home, and they had financial problems. Factors that were not linked to divorce in these older adults were the onset of an empty nest, the wife's or husband's retirement, and whether the wife or husband had a chronic health condition. Also, as with younger adults, middle-aged adults who are divorced have more physical and mental health problems than those who are married. In a recent Korean study of middle-aged adults, those who were divorced were more likely to smoke, binge drink, get inadequate sleep, and be depressed than their married counterparts (Kim, Lee, & Park, 2018).

Divorce in Older Adults An increasing number of older adults are divorced (Smock & Schwartz, 2020). In 1980, 3 percent of women 65 years and older were divorced, but that rate had increased to 13 percent by 2015. Similarly, in 1980 4 percent of men 65 years and older were divorced, but that rate had increased to 11 percent by 2015 (U.S. Census Bureau, 2016). Many of these individuals were divorced or separated before they entered late adulthood. In a recent study, older adult divorced individuals were more accepting of divorce than their counterparts two decades earlier (Brown & Wright, 2019).

Divorce brings social, financial, and physical consequences for older adults (Suitor, Gilligan, & Pillemer, 2016). Divorce can weaken kinship ties when it occurs in later life, especially in the case of older men. Divorced older women are less likely to have adequate financial resources than married older women, and older adults who are divorced have more health problems than those who are not (Bennett, 2006). Further, a recent study of older adults in Great Britain (average age: 63) found that those were divorced were more likely to die earlier and have lower life satisfaction than their married counterparts (Bourassa, Ruiz, & Sbarra, 2019).

In further research, many of the same factors traditionally associated with divorce in younger adults were also likely to occur in older adults (Lin & others, 2019). The longer older adults had been married, the more likely they were to have better marital quality, own a home, and be wealthy, and the less likely they were to become divorced. Another recent study found that partnered older adults were more likely to receive relatively high Social Security benefits and less likely to live in poverty (Lin, Brown, & Hammersmith, 2017).

REMARRIED ADULTS

Data indicate that the remarriage rate in the United States has declined by more than 50 percent from 1950 to 2017 (Schweizer, 2019). Thus, both a retreat from marriage and a retreat from remarriage have been occurring in the United States (Smock & Schwartz, 2020). The main reason for the decline is the dramatic increase in cohabitation in recent years. Men are more likely to remarry than women; in 2013, the remarriage rate was almost twice as high for men as women (40 per 1,000 for men and 21 per 1,000 for women) (Livingston, 2017). Thus, men are either more eager or more able to find new spouses than are women.

Adults who remarry usually do so rather quickly, with approximately 50 percent remarrying within three years after the divorce (Sweeney, 2009, 2010). Men remarry sooner than women. Men with higher incomes are more likely to remarry than their counterparts with lower incomes. Remarriage occurs sooner for partners who initiate a divorce (especially in the

first several years after divorce and for older women) than for those who do not initiate it (Sweeney, 2009, 2010). And some remarried individuals are more adult-focused, responding more to the concerns of their partner, while others are more child-focused, responding more to the concerns of their children (Anderson & Greene, 2011).

Adjustment Evidence on the benefits of remarriage is mixed. Subsequent marriages are more likely to be unstable than first marriages, with divorce more likely to occur—especially during the first several years—than in first marriages (Waite, 2009). While approximately 50 percent of first marriages end in divorce within 20 years, that figure rises to 67 percent for second marriages and 73 percent for third marriages (Banschick & Tabatsky, 2011).

Adults who remarry have lower levels of mental health (higher rates of depression, for example) than adults in first marriages, but remarriage often improves the financial status of remarried adults, especially women (Waite, 2009). Researchers also have found that remarried adults' marital relationships tend to be more egalitarian and more likely to be characterized by shared decision making than first marriages (Waite, 2009).

Among the strategies that can help remarried couples cope with the stress of living in a stepfamily are these (Visher & Visher, 1989):

- *Have realistic expectations*. Allow time for loving relationships to develop, and look at the complexity of the stepfamily as a challenge to overcome.
- *Develop new positive relationships within the family*. Create new traditions and ways of dealing with difficult circumstances. Allocation of time is especially important because so many people are involved. The remarried couple needs to allot some time for each person to spend alone.

Remarriage and Aging Rising divorce rates, increased longevity, and better health have led to an increase in remarriage by older adults (Papernow, 2018). A recent study of middle-aged and older adults found that 22 percent of women and 37 percent of men repartnered within 10 years following divorce (Brown & others, 2019). Repartnering occurred more often through cohabitation than through remarriage, especially for men.

What happens when an older adult wants to remarry or does remarry? Researchers have found that some older adults perceive negative social pressure about their decision to remarry. These negative sanctions range from raised eyebrows to rejection by adult children. However, the majority of adult children support the decision of their older adult parents to remarry. Researchers have found that remarried parents and stepparents provide less financial and emotional support to adult stepchildren than do parents in first marriages (Ganong & Coleman, 2018).

LGBTQ ADULTS

Until recently, the legal context of marriage created barriers to breaking up that did not exist for same-gender partners. However, the legalization of same-gender marriage in all 50 states in 2015 extended this context to same-gender partners (Colistra & Johnson, 2021). In many additional ways, researchers have found that same-gender relationships are similar—in their satisfactions, loves, joys, and conflicts—to different-gender relationships (Baker & Halford, 2020). For example, a recent study indicated that adults in same-gender relationships were experiencing levels of commitment, satisfaction, and emotional intimacy similar to those of adults in different-gender relationships (Joyner, Manning, & Prince, 2019). And like heterosexual couples, many same-gender couples are creating families that include children (Farr & Vasquez, 2020a, b).

Couples composed of women especially place a high priority on equality in their relationships. One study revealed that over the course of ten years of cohabitation, partners in same-gender relationships showed a higher average level of relationship quality than different-gender couples did (Kurdek, 2008). Also, another survey found that a greater percentage of same-gender, dual-earner couples than different-gender couples said they share laundry (44 versus 31 percent), household repairs (33 versus 15 percent), and routine (74 versus 38 percent) and sick (62 versus 32 percent) child care responsibilities (Matos, 2015).

There are a number of misconceptions about same-gender couples (Goldberg & Allen, 2020). Contrary to stereotypes, one partner is masculine and the other feminine in only a small percentage of same-gender couples. Only a small segment of gay men have a large number

What are some characteristics of same-gender relationships?
(*Top*): Creatas Images/Getty Images;
(*bottom*): Wavebreakmedia/Shutterstock

of sexual partners, and this is uncommon among lesbians. Furthermore, researchers have found that same-gender couples prefer long-term, committed relationships (Fingerhut & Peplau, 2013). About half of committed couples composed of gay men do have an open relationship that allows the possibility of sex (but not affectionate love) outside of the relationship. Lesbian couples usually do not have this type of relationship.

A special concern is the stigma, prejudice, and discrimination that LGBTQ (lesbian, gay, bisexual, transgender, queer) individuals experience because of widespread social devaluation of same-gender relationships (Vargas & others, 2021). However, one study indicated that many individuals in these relationships saw stigma as bringing them closer together and strengthening their relationship (Frost, 2011).

Review *Connect* Reflect

LG2 Discuss the diversity of adult relationships and families and how they influence people's lives.

Review

- Stepfamilies
- LGBTQ Families
- Adoptive Parents and Adopted Children

Just as there are diverse types of adult relationships and families, so are there diverse styles of parenting and diverse types of parents. Before we examine these diverse styles and types, let's explore the roles of parents.

PARENTAL ROLES

Many adults plan when to become parents and consider how parenting will fit with their economic situation. For others, the discovery that they are about to become parents is a startling surprise. In either event, the prospective parents may have mixed emotions and romantic illusions about having a child (Carl, 2012). The needs and expectations of parents have stimulated many myths about parenting.

Some recent media accounts have portrayed many parents as unhappy, feeling little joy in caring for their children. However, researchers have found that parents are more satisfied with their lives than people who are not parents, feel relatively better on a daily basis than do people who are not parents, and have more positive feelings related to caring for their children than from other daily activities (Nelson & others, 2013). Also, a research review concluded that parents are unhappy when they experience more negative emotions, financial problems, sleep problems, and troubled marriages (Nelson, Kushlev, & Lyubomirsky, 2014). In this review, it was concluded that parents are happy when they experience meaning in life, satisfaction of basic needs, more positive emotions than negative ones, and positive social roles.

Currently, there is a tendency for couples to have fewer children. The number of one-child families is increasing. Is there a best time to have children? What are some of the restrictions individuals face when they become parents? These are some of the questions we now consider.

Timing of Parenthood Like the age when individuals first marry, the age at which individuals begin to have children has been increasing (Williams, Sawyer, & Wahlstrom, 2020). Births occurred more frequently among women in their thirties than among women in their twenties in 2016 for the first time ever. In 2018, the average age for women having a first child was the highest it had ever been: 26.9 years of age (National Center for Health Statistics, 2019). Also, a national poll of 40- to 50-year-old U.S. women found that those with a master's degree or higher first became mothers at 30; in comparison, the average age of first-time mothers with a high school diploma was just 24 (Pew Research Center, 2015a). While the average age of having a first child has increased in the United States, it is much higher in the United Kingdom: 30.6 years of age in 2018 (U.K. Office of National Statistics, 2018).

As birth control has become common practice, many individuals consciously choose when they will have children and how many children they will rear. The number of one-child families is increasing, for example, and U.S. women overall are having fewer children or not having children at all. What are some of the advantages of having children early or late? Some of the advantages of having children early (in the twenties) are these: (1) the parents are likely to have more physical energy—for example, they can cope better with such matters as getting up in the middle of the night with infants and waiting up until adolescents come home at night; (2) the birth parent is likely to have fewer medical problems with pregnancy and childbirth; and (3) the parents may be less likely to build up expectations for their children, as do many couples who have waited many years to have children.

There are also advantages of postponing childbearing until the thirties: (1) the parents have had more time to consider their goals in life, such as what they want from their family and career roles; (2) the parents are more mature and are able to benefit from their experiences to engage in more competent parenting; and (3) the parents are better established in their careers and have more income for child-rearing expenses.

The Transition to Parenting Whether people become parents through pregnancy, adoption, or stepparenting, they face disequilibrium and must adapt. In a longitudinal investigation of couples from late pregnancy until 3½ years after the baby was born, most couples enjoyed more positive marital relations before the baby was born than after (Cowan & Cowan, 2000, 2009). Still, almost one-third showed an increase in marital satisfaction. Some couples said that the baby had both brought them closer together and moved them farther apart; being parents enhanced their sense of themselves and gave them a new, more stable identity as a couple. Babies opened men up to a concern with intimate relationships, and the demands of juggling work and family roles stimulated women to manage family tasks more efficiently and pay attention to their own personal growth.

What characterizes the transition to parenting?
Chris Ryan/OJO Images/Getty Images

The Bringing Baby Home project is a workshop for new parents that helps couples strengthen their relationship, understand and become acquainted with their baby, resolve conflict, and develop parenting skills (Gottman, 2021b). Evaluations of the project revealed that participants were better able to work together as parents, fathers were more involved with their baby and sensitive to the baby's behavior, mothers had a lower incidence of postpartum depression symptoms, and babies showed better overall development than the babies of participants in a control group (Gottman, 2021b). More recent research involving the Bringing Home Baby Project found that fathers who participated in the program felt more appreciated by their wives and that mothers were more satisfied with the division of labor when fathers were more involved in parenting (Shapiro, Gottman, & Fink, 2020).

Other studies have explored the transition to parenthood (Olsavasky & others, 2020; Pu & Rodriguez, 2021). In one study, mothers experienced unmet expectations in the transition to parenting, with fathers doing less than their partners had anticipated (Biehle & Mickelson, 2012). Further, a recent study of parents in different-gender couples revealed that a higher level of anxiety and depression symptoms in mothers in the last trimester of pregnancy was associated with infants' externalizing problems at 2 years of age and that a higher level of these symptoms in fathers in the third trimester of pregnancy was related to a higher level of infants' internalized and externalized problems at 14 months of age (Hughes & others, 2020).

Parents as Managers of Children's Lives Parents can play important roles as managers of children's opportunities, as monitors of their lives, and as social initiators and arrangers (Atherton, Lawson, & Robins, 2020). An important developmental task of childhood and adolescence is to learn how to make competent decisions in an increasingly independent manner. To help children and adolescents reach their full potential, an important parental role is to be an effective manager—one who finds information, makes contacts, helps structure choices, and provides guidance (Pizarro, Surkan, & Bustamante, 2021). Parents who fulfill this important managerial role help children and adolescents to avoid pitfalls and to work their way through the myriad choices and decisions they face.

Parents as Regulators of Children's Activities Parents can serve as regulators of opportunities for their children's activities (Collins & Madsen, 2019). From infancy through adolescence, mothers are more likely than fathers to have a managerial role in guiding and managing the activities in which children participate. In infancy, this might involve taking a child to a doctor and arranging for child care; in early childhood, it might involve a decision about which preschool the child should attend and contacting other parents who have young children whom their child can play with; in middle and late childhood, it might include directing the child to take a bath, to match their clothes and wear clean clothes, and to put away toys; in adolescence, it could involve participating in a parent-teacher conference and subsequently managing the adolescent's homework activity. Researchers have found that family-management practices are related to students' grades and self-responsibility (Lowe & Dotterer, 2013).

Parental Monitoring and Adolescents' Information Management A key aspect of the managerial role of parenting is effective monitoring, which is especially important as children move into the adolescent years (Atherton, Lawson, & Robins, 2020). Monitoring includes supervising adolescents' choice of social settings, activities, and friends as well as their academic efforts. In one study of fifth- to eighth-graders, a higher level of parental monitoring was associated with students' earning higher grades (Top, Liew, & Luo, 2017). In another study, low parental monitoring was a key factor in predicting a developmental trajectory of delinquency and substance use in adolescence (Wang & others, 2014). In other research, lower parental monitoring was associated with earlier initiation of alcohol use, binge drinking, and marijuana use in 13- to 14-year-olds (Rusby & others, 2018). Also, a recent study revealed that when parents had little awareness of the whereabouts of their daughters, adolescent girls were more likely to smoke cigarettes and to initiate smoking at an earlier age (Sartor & others, 2020). In addition, recent research indicated that a higher level of general parental monitoring of adolescents' spending habits, friends, and whereabouts was linked to adolescents having healthier weight status, better dietary habits, more physical exercise, and less screen time (Kim & others, 2019). Further, a research meta-analysis revealed that a higher level of parental monitoring and rule enforcement were linked to later initiation of sexual intercourse and increased use of condoms by adolescents (Dittus & others, 2015). And a recent study indicated that parental active tracking measures during adolescence and college were linked to better health behavior in both developmental time frames (Abar & others, 2021).

What characterizes adolescents' management of their parents' access to information?
Ryan McVay/Getty Images

A current interest involving parental monitoring focuses on adolescents' management of their parents' access to information, especially disclosing or concealing details about their activities (Campione-Barr & Smetana, 2019). When parents engage in positive parenting practices, adolescents are more likely to disclose information. For example, disclosure increases when parents ask adolescents questions and when adolescents' relationship with parents is characterized by a high level of trust, acceptance, and quality (Smetana, Robinson, & Rote, 2015). Researchers have found that adolescents' disclosure to parents about their whereabouts, activities, and friends is linked to positive adolescent adjustment (Laird & Marrero, 2010). Also, recent research indicated that adolescents who engaged in problem behavior were more secretive and disclosed less information to parents (Darling & Tilton-Weaver, 2019).

PARENTING STYLES AND DISCIPLINE

A few years ago, there was considerable interest in Mozart CDs that were marketed with the promise that playing them would enrich infants' and young children's brains. Some of the parents who bought them probably thought, "I don't have enough time to spend with my children, so I'll just play these CDs and then they won't need me as much." Similarly, one-minute bedtime stories have been marketed for parents to read to their children (Walsh, 2000). There are one-minute bedtime bear books, puppy books, and so on. Parents who buy them know it is a good idea to read to their children, but they don't want to spend a lot of time doing it. Behind the popularity of these products is an unfortunate theme that suggests that parenting can be done quickly, with little or no inconvenience (Sroufe, 2000).

What is wrong with these quick-fix parenting strategies? Good parenting takes time and effort (Grusec, 2020). You can't do it in a minute here and a minute there. You can't do it with CDs or DVDs.

One survey of American parents found that approximately half of fathers and one-fourth of mothers reported feeling that they were not spending enough time with their children (Pew Research Center, 2013). Nonetheless, in this survey, both mothers and fathers were spending more time with their children than the previous generation of parents did.

Of course, it's not just the quantity of time parents spend with children that is important for children's development—the quality of the parenting is clearly important (Laible, Carlo, & Padilla-Walker, 2020). To further understand variations in parenting, let's consider the styles parents use when they interact with their children, how they discipline their children, and how they engage in coparenting.

Baumrind's Parenting Styles Diana Baumrind (1971, 2012) argues that parents should be neither punitive nor aloof. Rather, they should develop rules for their children and be affectionate with them. She has described four parenting styles:

- **Authoritarian parenting** is a restrictive, punitive style in which parents exhort the child to follow their directions and respect their work and effort. The authoritarian parent places firm limits and controls on the child and allows little verbal exchange. For example, an authoritarian parent might say, "You will do it my way or else." Authoritarian parents also might spank the child frequently, enforce rules rigidly but not explain them, and show rage toward the child. Children of authoritarian parents are often unhappy, fearful, and anxious about comparing themselves with others, fail to initiate activity, and have weak communication skills. Sons of authoritarian parents may behave aggressively (Hart & others, 2003). A recent study revealed that authoritarian parenting was associated with being a bully perpetrator (Krisnana & others, 2021). And in another recent study, authoritarian parenting was associated with all types of child maltreatment (Lo & others, 2019).

authoritarian parenting A restrictive, punitive style in which parents exhort the child to follow their directions and to respect their work and effort. Firm limits are placed on the child, and little verbal exchange is allowed.

authoritative parenting A style that encourages children to be independent but still places limits and controls on children's actions; extensive verbal give-and-take is allowed, and parents are warm and nurturant toward the child.

neglectful parenting A style in which the parent is uninvolved in the child's life.

indulgent parenting A style in which parents are highly involved with their children but place few demands or controls on them.

- **Authoritative parenting** encourages children to be independent but still places limits and controls on their actions. Extensive verbal give-and-take is allowed, and parents are warm and nurturant toward the child. An authoritative parent might put his arm around the child in a comforting way and say, "You know you should not have done that. Let's talk about how you can handle the situation better next time." Authoritative parents show pleasure and support in response to children's constructive behavior. They also expect mature, independent, and age-appropriate behavior by children. Children whose parents are authoritative are often cheerful, self-controlled, self-reliant, and achievement-oriented; they tend to maintain friendly relations with peers, cooperate with adults, and cope well with stress. A recent Chinese study revealed that authoritative parenting increased children's favorable trajectories of math achievement (Wang, Chen, & Gong, 2021).

  Also, a recent study of Mexican American families revealed that authoritative parents were more likely to have adolescents who engaged in higher levels of prosocial behavior than parents using the other styles described here (Carlo & others, 2018). Further, in a recent study, authoritative parenting was associated with a lower risk of all types of child maltreatment (Lo & others, 2019). And recent research indicated that authoritative parenting was linked to reducing adolescent screen time (Xu, 2021).
- **Neglectful parenting** is a style in which the parent is very uninvolved in the child's life. Children whose parents are neglectful feel that other aspects of the parents' lives are more important than they are. These children tend to be socially incompetent. Many have poor self-control and don't handle independence well. They frequently have low self-esteem, are immature, and may be alienated from their family. In adolescence, they may show patterns of truancy and delinquency.
- **Indulgent parenting** is a style in which parents are highly involved with their children but place few demands or controls on them. Such parents let their children do what they want. The result is that the children never learn to control their own behavior and always expect to get their way. Some parents deliberately rear their children in this way because they believe the combination of warm involvement and few restraints will produce a creative, confident child. However, children whose parents are indulgent rarely learn respect for others and tend to have difficulty controlling their behavior. They might be domineering, egocentric, and noncompliant, and have difficulties in peer relations. A recent study of 7- to 9-year-olds found that indulgent parenting was associated with increased body mass index (BMI) (Hughes & others, 2021).

	Accepting, responsive	Rejecting, unresponsive
Demanding, controlling	Authoritative	Authoritarian
Undemanding, uncontrolling	Indulgent	Neglectful

FIGURE **6**

CLASSIFICATION OF PARENTING STYLES.
The four types of parenting styles (authoritative, authoritarian, indulgent, and neglectful) involve the dimensions of acceptance and responsiveness, on the one hand, and demand and control on the other. For example, authoritative parenting involves being both accepting/responsive and demanding/controlling.
Steve Debenport/E+/Getty Images

These four classifications of parenting involve combinations of acceptance and responsiveness on the one hand and demand and control on the other (Maccoby & Martin, 1983). How these dimensions combine to produce authoritarian, authoritative, neglectful, and indulgent parenting is shown in Figure 6.

Parenting Styles in Context Do the benefits of authoritative parenting transcend the boundaries of ethnicity, socioeconomic status, and household composition? Although some exceptions have been found, evidence linking authoritative parenting with competence on the part of the child occurs in research across a wide range of ethnic groups, social strata, cultures, and family structures (Garcia, Lopez-Fernandez, & Serra, 2021).

Other research with ethnic groups suggests that some aspects of the authoritarian style may be associated with positive child outcomes. Elements of the authoritarian style may take on different meanings and have different effects depending on the context (Pinquart & Kauser, 2018). For example, Asian American parents often continue aspects of traditional Asian child-rearing practices that have sometimes been described as authoritarian. The parents exert considerable control over their children's lives. However, Ruth Chao (2007) argues that the style of parenting used by many Asian American parents is distinct from the domineering control of the authoritarian style. Instead, Chao argues that the control reflects concern and involvement in their children's lives and is best

conceptualized as a type of training. The high academic achievement of Asian American children may be a consequence of their "training" parents (Stevenson & Zusho, 2002).

According to Ruth Chao, what type of parenting style do many Asian American parents use?
Tanya Constantine/Getty Images

Further Thoughts on Parenting Styles Several caveats about parenting styles are in order. First, the parenting styles do not capture the important themes of reciprocal socialization and synchrony (Dora & Baydar, 2020). Keep in mind that children socialize parents, just as parents socialize children (Nelemans & others, 2020). Second, many parents use a combination of techniques rather than a single technique, although one technique may be dominant. Although consistent parenting is usually recommended, the wise parent may sense the importance of being more permissive in certain situations, more authoritarian in some circumstances, and more authoritative in others. Moreover, parenting styles often are talked about as if both parents have the same style, but this is not always the case. Also, some critics argue that the concept of parenting style is too broad and that more research needs to be conducted to "unpack" parenting styles by studying the influence of various components of the styles (Maccoby, 2007). For example, is parental monitoring more important than warmth in predicting child and adolescent outcomes? Further, much of the parenting style research has involved mothers, not fathers. In many families with different-gender parents, mothers will use one style, fathers another style. Especially in traditional cultures, fathers often have an authoritarian style and mothers a more permissive, indulgent style. It has often been said that it is beneficial for parents to engage in similar parenting styles; however, if fathers are authoritarian and aren't willing to change, children benefit when mothers use an authoritative style.

Punishment Use of corporal (physical) punishment is legal in every state in the United States. A national survey of U.S. parents with 3- and 4-year-old children found that 26 percent of parents reported spanking their children frequently, and 67 percent reported yelling at their children frequently (Regalado & others, 2004). A study of more than 11,000 U.S. parents indicated that 80 percent of the parents reported spanking their children by the time they reached kindergarten (Gershoff & others, 2012), and a research review concluded that there is widespread approval of corporal punishment by U.S. parents (Chiocca, 2017). A recent U.S. study conducted during the COVID-19 pandemic found that nearly 20 percent of parents reported having hit or spanked their children in the past two weeks and indicated that they had used spanking more in the past two weeks (Lee & others, 2021).

A cross-cultural comparison found that individuals in the United States were among those with the most favorable attitudes toward corporal punishment and were most likely to remember it being used by their parents (see Figure 7) (Curran & others, 2001). Physical punishment was outlawed in 59 countries in 2020 (up from 34 in 2012), with a number of countries increasing the ban on physical punishment mainly to promote children's rights to protection from abuse and exploitation (Global Initiative to End All Corporal Punishment of Children, 2020). Also, in a recent study, interviews with college students indicated that daughters were less likely than sons to be physically punished by both parents (Mehlhasen-Hassoen, 2021).

What are some reasons for avoiding spanking or similar punishments? They include the following:

- When adults punish a child by yelling, screaming, or spanking, they are presenting children with out-of-control models for handling stressful situations. Children may imitate this behavior.
- Punishment can instill fear, rage, or avoidance. For example, spanking the child may cause the child to avoid being near the parent and to fear the parent.
- Punishment tells children what not to do rather than what to do. Children should be given constructive feedback, such as "Why don't you try this?"
- Parents might unintentionally become so angry when they are punishing the child that they become abusive.

Most child psychologists recommend handling misbehavior by reasoning with the child, especially explaining the consequences of the child's actions

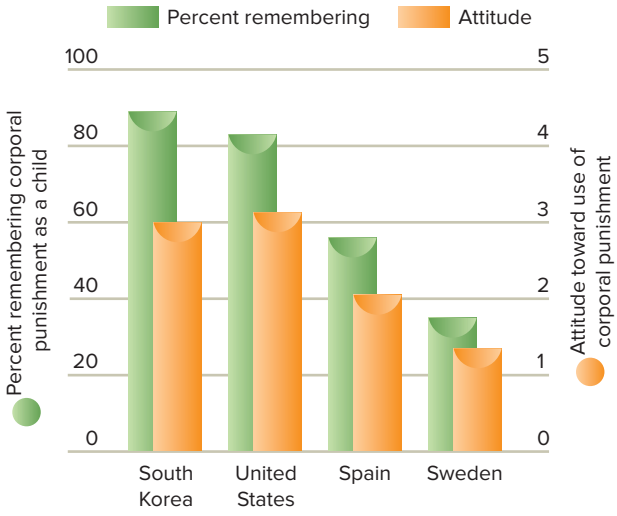

FIGURE 7

CORPORAL PUNISHMENT IN DIFFERENT COUNTRIES. A 5-point scale was used to assess attitudes toward corporal punishment, with scores closer to 1 indicating an attitude against its use and scores closer to 5 suggesting an attitude favoring its use. *Why are studies of corporal punishment correlational studies, and how does that affect their usefulness?*

How do most child psychologists recommend handling a child's misbehavior?
Zoey/Image Source/Alamy Stock Photo

for others. *Time out*, in which the child is removed from a setting that offers positive reinforcement, can also be effective. For example, when the child has misbehaved, a parent might forbid TV viewing for a specified time. Debate about the effects of punishment on children's development continues (Gershoff & others, 2018, 2019; Lansford, 2020; Larzelere & others, 2019; Rohner & Melendez-Rhodes, 2019). Several longitudinal studies also have found that physical punishment of young children is associated with higher levels of aggression later in childhood and adolescence (Gershoff & others, 2012; Thompson & others, 2017).

However, a meta-analysis that focused on longitudinal studies revealed that the negative outcomes of punishment on children's internalizing and externalizing problems were minimal (Ferguson, 2013). Also, a research review of 26 studies concluded that only severe or predominant use of spanking, not mild spanking, compared unfavorably with alternative discipline practices (Larzelere & Kuhn, 2005). Nonetheless, in a research meta-analysis, physical punishment that was not abusive was still linked to detrimental child outcomes (Gershoff & Grogan-Kaylor, 2016).

Thus, in the view of some experts, it is still difficult to determine whether the effects of physical punishment are harmful to children's development, although such a view might be distasteful to some individuals (Ferguson, 2013; Larzelere & others, 2019). Also, as with other research on parenting, research on punishment is correlational in nature, making it difficult to discover causal factors.

In thinking about the effects of physical punishment, consider the concept of reciprocal socialization discussed at the beginning of this chapter, which emphasizes bidirectional child and parent influences (Lansford & others, 2018). Researchers have found links between children's early behavioral problems and parents' subsequent greater use of physical punishment over time (Laible, Thompson, & Froimson, 2015). Nonetheless, a large majority of leading experts on parenting conclude that physical punishment has harmful effects on children and should not be used (Gershoff & others, 2019).

In a research review, Elizabeth Gershoff (2013) concluded that the defenders of spanking have not produced any evidence that spanking produces positive outcomes for children, while negative outcomes of spanking have been replicated in many studies. Also, it is clear that when physical punishment involves abuse, it can be very harmful to children's development, as discussed later in this chapter (Hicks & others, 2020).

What characterizes coparenting?
Hero/Corbis/Glow Images

Coparenting

The relationship between marital conflict and the use of punishment highlights the importance of **coparenting,** which is the support that parents provide one another in jointly raising a child. Poor coordination between parents, undermining of the other parent, lack of cooperation and warmth, and disconnection by one parent are conditions that place children at risk for problems. For example, one study revealed that coparenting influenced young children's effortful control above and beyond maternal and paternal parenting by themselves (Karreman & others, 2008). Further, a recent study revealed that coparenting involving couple supportiveness, especially when their children were 3 to 5 years of age, was linked to reduced levels of externalizing problems 8 to 10 years later (Parkes, Green, & Mitchell, 2019). And a recent study of low-income, unmarried parents revealed that cooperative coparenting at earlier points in time results in fewer child behavior problems later on (Choi, Parra, & Jiang, 2019).

Parents who do not spend enough time with their children or who have problems in child rearing can benefit from counseling and therapy. To read about the work of marriage and family therapist Darla Botkin, see the *Connecting with Careers* profile.

Child Maltreatment

Unfortunately, punishment sometimes leads to the abuse of infants and children (Asnes & others, 2021). In 2018, approximately 678,000 U.S. children were found to be victims of child abuse at least once during that year (Administration for Children & Families, 2020). Ninety-one percent of abused children were harmed by one or both parents. Laws in many states now require physicians and teachers to report suspected cases of child abuse, yet many cases go unreported, especially those involving battered infants (Nouman & others, 2020).

Whereas the public and many professionals use the term **child abuse** to refer to both abuse and neglect, developmentalists increasingly use the term **child maltreatment** (Posick & others, 2021; Rebbe, Martinson, & Mienko, 2021). This term does not have the same level of emotional impact as the term *abuse* and acknowledges that maltreatment includes diverse conditions.

coparenting The support that parents provide one another in jointly raising a child.

child abuse The term used most often by the public and many professionals to refer to both abuse and neglect.

child maltreatment The term increasingly used by developmentalists in referring not only to abuse and neglect but also to diverse conditions that are detrimental to children.

Darla Botkin, Marriage and Family Therapist

Darla Botkin is a marriage and family therapist who teaches, conducts research, and engages in marriage and family therapy. She is on the faculty of the University of Kentucky. Botkin obtained a bachelor's degree in elementary education with a concentration in special education and went on to receive a master's degree in early childhood education. She spent the next six years working with children and their families in a variety of settings, including child care, elementary school, and Head Start. These experiences led Botkin to recognize the interdependence of the developmental settings that children and their parents experience (such as home, school, and work). She returned to graduate school and obtained a Ph.D. in family studies from the University of Tennessee. She then became a faculty member in the Family Studies program at the University of Kentucky. Upon completing further coursework and clinical training in marriage and family therapy, she became certified as a marriage and family therapist.

Botkin's current interests include working with young children in family therapy, understanding gender and ethnic issues in family therapy, and exploring the role of spirituality in family wellness.

For more information about what marriage and family therapists do, see the Careers in Life-Span Development appendix.

Types of Child Maltreatment The four main types of child maltreatment are physical abuse, child neglect, sexual abuse, and emotional abuse (National Clearinghouse on Child Abuse and Neglect, 2020):

- **Physical abuse** is characterized by the infliction of physical injury as a result of punching, beating, kicking, biting, burning, shaking, or otherwise harming a child. The parent or other adult may not have intended to hurt the child; the injury may have resulted from excessive physical punishment (Lakhdir & others, 2021). In 2018, 11 percent of maltreated children were physically abused (Administration for Children & Families, 2020). A recent study found that adults who had been physically abused in the first five years of their life were more likely to have received special education services, to have repeated a grade in school, to have been convicted of a crime in the past year, and to have worse physical health compared to adults who had not been physically abused in the first five years of their life (Lansford & others, 2021).
- **Child neglect** is characterized by failure to provide for the child's basic needs. Child neglect is extensive—in 2018, 61 percent of maltreated children were neglected (Administration for Children and Families, 2020). Neglect can be physical (abandonment, for example), educational (allowing chronic truancy, for example), or emotional (marked inattention to the child's needs, for example) (Font & Maguire-Jack, 2020). Child neglect is by far the most common form of child maltreatment (Gonzalez, Bethencourt Mirabal, & McCall, 2021). In every country where relevant data have been collected, neglect occurs up to three times as often as abuse. A recent research review of risk factors for engaging in child neglect found that most risks involved parent factors, including a history of antisocial behavior or criminal offending, having mental or physical problems, and experiencing abuse as children (Mulder & others, 2018).

physical abuse Infliction of physical injury by punching, beating, kicking, biting, burning, shaking, or otherwise harming a child.

child neglect Failure to provide for a child's basic needs, including physical, educational, or emotional needs.

sexual abuse Fondling a child's genitals, intercourse, incest, rape, sodomy, exhibitionism, and commercial exploitation through prostitution or the production of pornographic materials.

emotional abuse Acts or omissions by parents or other caregivers that have caused, or could cause, serious behavioral, cognitive, or emotional problems.

- **Sexual abuse** includes fondling a child's genitals, intercourse, incest, rape, sodomy, exhibitionism, and commercial exploitation through prostitution or the production of pornographic materials (Melmer & Gutovitz, 2021). Unlike physical abuse, many cases of sexual abuse produce no outward physical signs that abuse has taken place. In 2018, 7 percent of maltreated children in the United States were sexually abused (Administration for Children & Families, 2020). A recent research review concluded that child sexual abuse is linked to increased incidence of mental health disorders (including posttraumatic stress disorder, mood and anxiety disorders) as well as substance use disorders (Noll, 2021).
- **Emotional abuse** (psychological/verbal abuse/mental injury) includes acts or omissions by parents or other caregivers that have caused, or could cause, serious behavioral, cognitive, or emotional problems (Ross, Kaminski, & Herrington, 2019). In a recent study, parental emotional abuse, more than any other type of abuse, was associated with increased rates of posttraumatic stress disorder (PTSD) during adolescence (Hoebner & others, 2021).

Although any of these forms of child maltreatment may be found separately, they often occur in combination. Emotional abuse is almost always present when other forms are identified.

The Context of Abuse No single factor causes child maltreatment. A combination of factors, including the culture, neighborhood, family, and development, likely contribute to child maltreatment. The extensive violence that takes place in American culture is reflected in the occurrence of violence in the family (Tremblay, 2021). A regular diet of violence appears on television screens, and parents often resort to power assertion as a disciplinary technique. In China, where physical punishment is rarely used to discipline children, the incidence of child abuse is reportedly very low.

The family itself is obviously a key part of the context of abuse (Griffith, 2021; Osofsky & others, 2021). Among the family and family-associated characteristics that may contribute to child maltreatment are parenting stress, marital problems, substance abuse, social isolation, single parenting, and socioeconomic difficulties (especially poverty) (Carlson & others, 2020). The interactions of all family members should be considered, regardless of who performs the violent acts against the child. For example, even though the father may be the one who physically abuses the child, contributions by the mother, the child, and siblings also should be evaluated.

Were parents who abuse children abused by their own parents? A 30-year longitudinal study found that offspring of parents who had engaged in child maltreatment and neglect are at risk for engaging in child neglect and sexual maltreatment themselves (Widom, Czaja, & DuMont, 2015). Also, a recent study revealed that mothers who had experienced child maltreatment from their parents were more likely to engaged in maltreatment of their offspring, which in turn predicted increased rates of internalizing and externalizing symptoms in late childhood (Russotti & others, 2021). It is estimated that about one-third of parents who were abused when they were young abuse their own children (Cicchetti & Toth, 2016). Thus, some, but not a majority, of parents who were maltreated in childhood are locked into an intergenerational transmission of child maltreatment.

Developmental Consequences of Abuse Among the consequences of child maltreatment are poor emotion regulation, attachment problems, problems in peer relations, difficulty in adapting to school, and other psychological problems such as depression, delinquency, and substance abuse during childhood and adolescence (McTavish & others, 2020). As shown in Figure 8, maltreated young children in foster care were more likely to show abnormal stress hormone levels than middle-SES young children living with their birth family (Gunnar & Fisher, 2006). In this study, the abnormal stress hormone levels were mainly present in the foster children who experienced neglect, best described as "institutional neglect" (Fisher, 2005). Adolescents who experienced abuse or neglect as children are more likely than adolescents who were not maltreated as children to engage in violent romantic relationships, suicide attempts, delinquency, sexual risk taking, and substance abuse (Miller & others, 2013).

Later, during the adult years, individuals who were maltreated as children are more likely to experience physical, emotional, and sexual problems (Bakema & others, 2020; Nakayama & others, 2020). In a recent large-scale Canadian study, a history of child maltreatment involving either physical abuse or sexual abuse was linked to having physical and mental health

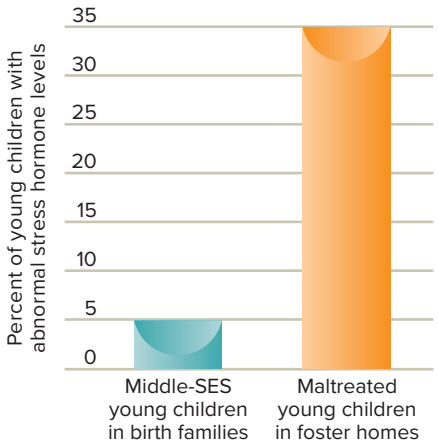

FIGURE **8**

ABNORMAL STRESS HORMONE LEVELS IN YOUNG CHILDREN IN DIFFERENT TYPES OF REARING CONDITIONS.

problems as adults (Cameranesi, Lix, & Piotrowski, 2019). As adults, maltreated children are at higher risk for violent behavior toward other adults—especially dating partners and marital partners—as well as for substance abuse, anxiety, and depression (Herrenkohl & others, 2021). Also, in a longitudinal study, experiencing abuse and neglect in the first five years of life were linked to having more interpersonal problems and lower academic achievement from childhood through their thirties (Raby & others, 2019). In addition, a recent study revealed that child maltreatment was associated with increased rates of psychiatric disorders and substance abuse in adulthood (Wang & others, 2020). And in a recent study of low-income families, the rate of intergenerational abuse was high and reflected a pathway of influence that increased children's maladaptive socioemotional development (as indicated in emotion dysregulation, for example) (Warmingham, Rogosch, & Cicchetti, 2020).

An important research agenda is to discover how to prevent child maltreatment or intervene in children's lives when they have been maltreated (Almy & Cicchetti, 2018). In one study of maltreating mothers and their 1-year-olds, two treatments were effective in reducing child maltreatment: (1) home visitation that emphasized improved parenting, coping with stress, and increased support for the mother; and (2) parent-infant psychotherapy that focused on improving maternal-infant attachment (Cicchetti, Toth, & Rogosch, 2005). Further, a recent study found that child maltreatment was associated with increased emotion-focused coping (crying, verbal aggression, for example) and decreased problem-focused coping (seeking help from an adult, for example (VanMeter, Handley, & Cicchetti, 2020). Thus, clinicians may want to integrate reducing emotion-focused coping into their intervention strategies with maltreated children. A recent large-scale study indicated that social support and coping skills were linked to positive adult mental health outcomes for maltreated children (Su, D'Arcy, & Meng, 2020).

PARENT–ADOLESCENT AND PARENT–EMERGING ADULT RELATIONSHIPS

Even the best parents may find their relationship with their child strained during adolescence, yet attachment to parents is an important aspect of adolescent development. As individuals become emerging adults, their relationship with their parents changes. Earlier in the chapter, we discussed the important strategy of parental monitoring in adolescence. Here we explore other aspects of parent-adolescent relationships.

Parent-Adolescent Relationships Important aspects of parent-adolescent relationships include autonomy/attachment and conflict. First, we explore the young adolescent's push for autonomy.

Autonomy and Attachment The young adolescent's push for autonomy and responsibility puzzles and angers many parents. Parents see their teenager slipping from their grasp. They may have an urge to assert stronger control as the adolescent seeks autonomy and responsibility. Heated emotional exchanges may ensue, with either side calling names, making threats, and doing whatever seems necessary to gain control. Most parents anticipate that their teenager will have some difficulty adjusting to the changes that adolescence brings, but few parents can imagine and predict just how strong will be an adolescent's desire to spend time with peers or how much adolescents will want to show that it is they—not their parents—who are responsible for their successes and failures.

The ability to attain autonomy and gain control over one's behavior in adolescence is acquired through appropriate adult reactions to the adolescent's desire for control (Rodriguez-Meirinhos & others, 2020). At the onset of adolescence, the average individual does not have the knowledge to make mature decisions in all areas of life. As the adolescent pushes for autonomy, the wise adult relinquishes control in those areas in which the adolescent can make reasonable decisions but continues to guide the adolescent to make reasonable decisions in areas where the adolescent's knowledge is more limited. Gradually, adolescents acquire the ability to make mature decisions on their own.

Expectations about the appropriate timing of adolescent autonomy often vary across cultures, parents, and adolescents (McElhaney & Allen, 2012). For example, expectations for early autonomy on the part of adolescents are more prevalent in non-Latinx Whites, single parents, and adolescents themselves than they are in Asian Americans or Latinxs, married parents, and parents themselves (Feldman & Rosenthal, 1999). Nonetheless, although Latinx cultures may

What strategies can parents use to guide adolescents in effectively handling their increased motivation for autonomy?
Hero Images/Getty Images

place a stronger emphasis on parental authority and restrict adolescent autonomy, one study revealed that regardless of where they were born, Mexican-origin adolescent girls living in the United States expected autonomy at an earlier age than their mothers preferred (Bamaca-Colbert & others, 2012). Another study of Mexican immigrant mothers and their U.S.-raised 13- to 14-year-old daughters explored expectations for autonomy when the daughters would reach 15 years of age (Romo, Mireles-Rios, & Lopez-Tello, 2014). In this study, the daughters hoped for less strict rules regarding social activities, while mothers reported that they still expected to exert control, although they were willing to allow more autonomy in personal matters such as physical appearance and to allow their daughter to group date.

Gender and ethnic differences characterize autonomy-granting in adolescence (Tran & Raffaelli, 2020). Boys are allowed to have more independence than girls. In one study, this was especially true in U.S. families with a traditional gender-role orientation (Bumpus, Crouter, & McHale, 2001). Also, Latinx parents protect and monitor their daughters more closely than do non-Latinx parents (Romo, Mireles-Rios, & Lopez-Tello, 2014).

One of the most widely discussed aspects of socioemotional development in infancy is secure attachment to caregivers (Dagan & Sagi-Schwartz, 2021). In the past several decades, researchers have explored whether secure attachment might also be an important element in adolescents' relationships with their parents (Withers, 2020). Researchers also have found that securely attached adolescents are less likely than those who are insecurely attached to have emotional difficulties and to engage in problem behaviors such as juvenile delinquency and drug abuse (Theoret & others, 2021). For example, a recent study of Lebanese adolescents revealed that those who were securely attached had lower rates of addiction to alcohol and cigarettes than their insecurely attached counterparts (Nakhoul & others, 2020). In another recent study, delinquent and maltreated adolescents had higher levels of insecure attachment (Protic & others, 2020).

In other research, Joseph Allen and his colleagues (2009) found that adolescents who were securely attached at age 14 were more likely to report at age 21 that they were in an exclusive relationship, comfortable with intimacy in relationships, and moving toward financial independence. In addition, a recent study revealed that when they had grown up in poverty, adolescents engaged in less risk-taking if they had a history of secure attachments to caregivers (Delker, Bernstein, & Laurent, 2018). And a research analysis concluded that the most consistent outcomes of secure attachment in adolescence involve positive peer relations and development of the adolescent's capacity for emotion regulation (Allen & Miga, 2010). In sum, just as in infancy, secure attachment is an important aspect of parent-adolescent relationships and is linked to a wide range of positive outcomes for adolescents (Laporta-Herrero & others, 2021).

Parent-Adolescent Conflict Although attachment to parents may remain strong during adolescence, the connectedness is not always smooth. Early adolescence is a time when conflict with parents escalates (Martin & others, 2019). Much of the conflict involves the everyday issues of family life, such as keeping a bedroom clean, dressing neatly, getting home by a certain time, and not talking incessantly on the phone. The conflicts rarely involve major dilemmas such as drugs and delinquency.

Conflict with parents increases in early adolescence. *What is the nature of this conflict in a majority of American families?*
Wavebreak Media/age fotostock

The increased conflict in early adolescence may be due to a number of factors: the biological changes of puberty, cognitive changes involving increased idealism and logical reasoning, social changes focused on independence and identity, maturational changes in parents, and expectations that are violated by parents and adolescents. Adolescents compare their parents with an ideal standard and then criticize their flaws. Many parents see their adolescent changing from a compliant child to someone who is noncompliant, oppositional, and resistant to parental standards. Also, early-maturing adolescents experience more conflict with their parents than do adolescents who mature late or on time (Collins & Steinberg, 2006).

It is not unusual to hear parents of young adolescents ask, "Is it ever going to get better?" Things usually do get better as adolescents move from early to late adolescence. Conflict with parents often escalates during early adolescence, remains somewhat stable during the high school years, and then lessens as the adolescent reaches 17 to 20 years of age. For example, in a recent study of Chinese American families, parent-adolescent conflict increased in early adolescence, peaked at about 16 years of age, and then decreased through late adolescence and emerging adulthood (Juang & others, 2018).

Old Model

Autonomy, detachment from parents; parent and peer worlds are isolated

Intense, stressful conflict throughout adolescence; parent-adolescent relationships are filled with storm and stress on virtually a daily basis

New Model

Attachment and autonomy; parents are important support systems and attachment figures; adolescent-parent and adolescent-peer worlds have some important connections

Moderate parent-adolescent conflict is common and can serve a positive developmental function; conflict greater in early adolescence

FIGURE **9**

OLD AND NEW MODELS OF PARENT-ADOLESCENT RELATIONSHIPS.

Martin Barraud/Caia Image/Glow Images

Also, parent-adolescent relationships become more positive if adolescents go away to college than if they live at home while attending college (Sullivan & Sullivan, 1980).

The everyday conflicts that characterize parent-adolescent relationships may serve a positive function. These minor disputes and negotiations facilitate the adolescent's transition from being dependent on parents to becoming an autonomous individual. Still, parent-adolescent conflict that is prolonged and intense may be associated with a number of adolescent problems, such as running away from home, juvenile delinquency, dropping out of school, adolescent pregnancy, membership in religious cults, and substance abuse (Akin & others, 2020; Delgado & others, 2019). Also, in a recent Chinese study, a lower level of parent-adolescent conflict was linked to less adolescent risk taking (Liu, Wang, & Tian, 2019).

In sum, the old model of parent-adolescent relationships suggested that parent-adolescent conflict is intense and stressful throughout adolescence. The new model emphasizes that most parent-adolescent conflict is moderate rather than intense and that the moderate conflict can serve a positive function. Figure 9 summarizes the old and new models of parent-adolescent relationships, which include changes in thinking about attachment and autonomy.

When families emigrate to another country, adolescents typically acculturate more quickly to the norms and values of their new country than do their parents (Nguyen & others, 2018). This likely occurs because of immigrant adolescents' exposure in school to the language and culture of the host country. The norms and values immigrant adolescents experience are especially likely to diverge from those of their parents in areas such as autonomy and romantic relationships. Such divergences are likely to increase parent-adolescent conflict in immigrant families.

Conclusions We have seen that parents play very important roles in adolescent development. Although adolescents are moving toward independence, they still need to stay connected with their families. Competent adolescent development is most likely when adolescents have parents who show them warmth and mutual respect, demonstrate sustained interest in their lives, recognize and adapt to their cognitive and socioemotional development, communicate expectations for high standards of conduct and achievement, and display constructive ways of dealing with problems and conflict.

Emerging Adults' Relationships with Their Parents

For the most part, emerging adults' relationships with their parents improve when they leave home. However, challenges in the parent–emerging adult relationship involve the emerging adult's possessing adult status in many areas while still depending on parents in some manner. Many emerging adults want to make their own decisions about where to live, whether to stay in college, which lifestyle to adopt, whether to get married, and so on (Padilla-Walker & Nelson, 2019). At the same time, parents often provide support for their emerging adult children even after they leave home. This might be accomplished through loans and monetary gifts for education or purchase of a car, financial contributions to living arrangements, and emotional support.

In successful emerging adulthood, individuals separate from their parents without cutting off ties completely or fleeing to some substitute emotional refuge. Complete cutoff from parents rarely solves emotional problems. Emerging adulthood is a time for young people to sort out emotionally what they will bring with them from their family of origin, what they will leave behind, and what they will create.

According to one adolescent girl, Stacey Christensen, age 16: "I am lucky enough to have open communication with my parents. Whenever I am in need or just need to talk, my parents are there for me. My advice to parents is to let your teens grow at their own pace, be open with them so that you can be there for them. We need guidance; our parents need to help but not be too overwhelming."

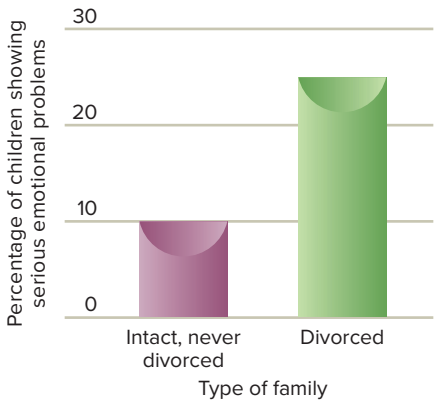

FIGURE 10

DIVORCE AND CHILDREN'S EMOTIONAL PROBLEMS. In Hetherington's research, 25 percent of children from divorced families showed serious emotional problems, compared with only 10 percent of children from nondivorced families. However, keep in mind that a substantial majority (75 percent) of the children from divorced families did not show serious emotional problems.

Now that we have explored many aspects of parenting at different points in development—childhood, adolescence, and emerging adulthood—we turn our attention to parent-child relationships in different types of families—working parents, children in divorced families, stepfamilies, gay and lesbian parents, and adoptive parents and adopted children.

WORKING PARENTS

More than one of every two U.S. mothers with a child under the age of 5 is in the labor force; more than two of every three with a child from 6 to 17 years of age work outside the home. Maternal employment is a part of modern life, but its effects continue to be debated.

In a recent national survey, working mothers (60 percent) were more likely than fathers (52 percent) to report that balancing work and family is difficult (Livingston & Bialik, 2018). Also in this survey, slightly more than half (54 percent) indicate that mothers do more than fathers when children's schedules and activities are involved. In another recent national survey, nearly one-fourth (24 percent) of working parents said that their children have asked them to work less, and a similar percentage (23 percent) report that work is negatively impacting their relationship with their children (Career Builder, 2018).

Most research on parental work has focused on young children and the mother's employment (Han, Hetzner, & Brooks-Gunn, 2019). However, the effects of parental work involve the father as well as the mother when matters such as work schedules, work-family stress, and unemployment are considered (O'Brien & others, 2014). Research indicates that the nature of parents' work matters more to children than whether one parent works outside the home (Parke, Roisman, & Rose, 2019).

Work can have positive and negative effects on parenting. Ann Crouter (2006) described how parents bring their experiences at work into their homes. She concluded that parents who have poor working conditions, such as long hours, overtime work, stressful work, and lack of autonomy on the job, are likely to be more irritable at home and to engage in less effective parenting than their counterparts who have better working conditions at their jobs. Also, a consistent finding is that children (especially girls) of working mothers engage in less gender stereotyping and have more egalitarian views of gender (Goldberg & Lucas-Thompson, 2008).

CHILDREN IN DIVORCED FAMILIES

Let's examine some important questions about children in divorced families:

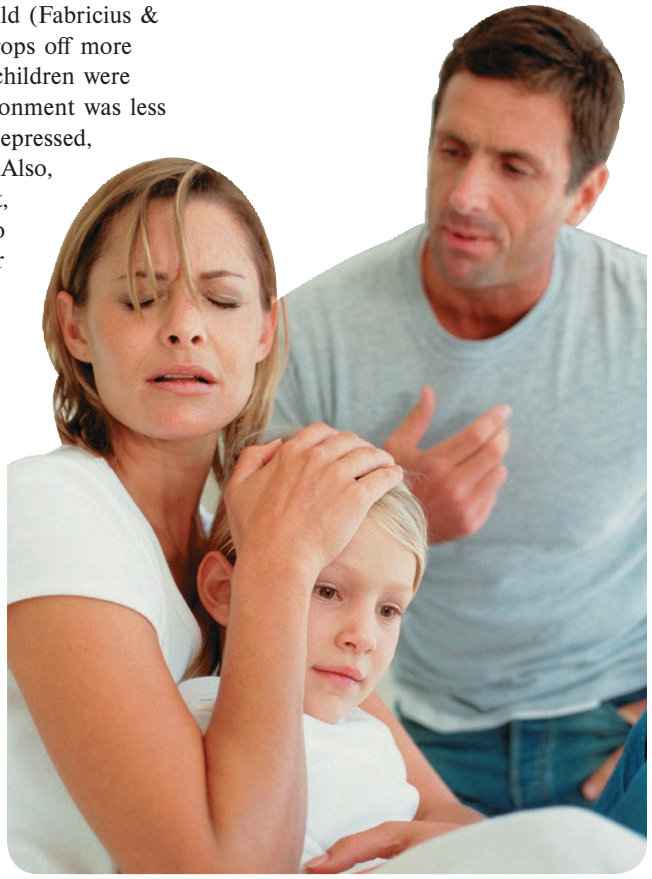
- ***Are children better adjusted in intact, never-divorced families than in divorced families?*** Most researchers agree that children from divorced families show poorer adjustment than their counterparts in nondivorced families (Hetherington, 2006; Meland, Breidablik, & Thuen, 2020; Lansford, 2019) (See Figure 10). Those who have experienced multiple divorces are at greater risk. Children in divorced families are more likely than children in nondivorced families to have academic problems, to show externalizing problems (such as acting out and delinquency) and internalizing problems (such as anxiety and depression), to be less socially responsible, to have less competent intimate relationships, to drop out of school, to become sexually active at an earlier age, to take drugs, to associate with antisocial peers, to have low self-esteem, and to be less securely attached as young adults (Boccia & others, 2021; Lansford, 2019). A recent meta-analysis of 54 studies and 506,299 participants concluded that children who experience parental divorce are especially at risk for depression, anxiety, suicide attempts, distress, alcohol abuse, drugs, and smoking (Auersperg & others, 2019). Also, a recent study found that adolescents' emotional and behavioral problems increased after their parents divorced, not before the divorce occurred (Tullius & others, 2021). Nonetheless, keep in mind that a majority of children in divorced families do not have significant adjustment problems (Ahrons, 2007).

  Note that marital conflict may have negative consequences for children in the context of marriage or divorce. A longitudinal study revealed that conflict in nondivorced families was associated with emotional problems in children (Amato, 2006). Indeed, many of the problems that children from divorced homes experience begin during the predivorce period, a time when parents are often in active conflict with each other. Thus, when

children from divorced homes show problems, the problems may be due not only to the divorce but also to the months or years of marital conflict that led to it.

E. Mark Cummings and his colleagues (Cummings & others, 2017; De Silva & others, 2020) have proposed *emotional security theory*, which has its roots in attachment theory and states that children appraise marital conflict in terms of their sense of security and safety in the family. These researchers make a distinction between marital conflict that is negative for children (such as hostile emotional displays and destructive conflict tactics) and marital conflict that can be positive for children (such as marital disagreement that involves a calm discussion of each person's perspective and working together to reach a solution).

- ***Should parents stay together for the sake of the children?*** Whether parents should stay in an unhappy or conflictual marriage for the sake of their children is one of the most commonly asked questions about divorce (Morrison, Fife, & Hertlein, 2017). If the stresses and disruptions in family relationships associated with an unhappy, conflictual marriage that erode the well-being of children are reduced by the move to a divorced, single-parent family, divorce can be advantageous. However, if the diminished resources and increased risks associated with divorce also are accompanied by inept parenting and sustained or increased conflict, not only between the divorced couple but also among the parents, children, and siblings, the best choice for the children would be that an unhappy marriage be retained (Hetherington & Stanley-Hagan, 2002). It is difficult to determine how these "ifs" will play out when parents either remain together in an acrimonious marriage or become divorced.
- ***How much do family processes matter in divorced families?*** In divorced families, family processes matter a great deal (Gong & Carano, 2020). When the divorced parents have a harmonious relationship and use authoritative parenting, the adjustment of children and adolescents is improved (Hetherington, 2006). When the divorced parents can agree on child-rearing strategies and can maintain a cordial relationship with each other, frequent visits by the noncustodial parent usually benefit the child (Fabricius & others, 2010). Following a divorce, father involvement with children drops off more than mother involvement, especially for fathers of girls. In one study, children were more likely to have behavior problems if their post-divorce home environment was less supportive and stimulating, their mother was less sensitive and more depressed, and if their household income was lower (Weaver & Schofield, 2015). Also, a research review concluded that coparenting (mutual parental support, cooperation, and agreement) following divorce was positively related to child outcomes such as lower anxiety and depression, as well as higher self-esteem and academic performance (Lamela & Figueiredo, 2016).
- ***Might parenting intervention programs improve the process of parenting and reduce children's problems after the divorce?*** In a 15-year follow-up longitudinal study, divorced families were randomly assigned to an 11-session parenting improvement program or a control condition involving literature when the children were 9- to 12-year-olds (Wolchik & others, 2021). The parenting program focused on improving mother-child relationship quality, increasing effective discipline, decreasing barriers to father involvement, and reducing interparental conflict. The mothers and children in the control group were both given three books on children's adjustment to divorce at one-month intervals. Initial effects of the parenting program included reduced rates of externalizing problems in late childhood and early adolescence, which in turn were linked to better academic outcomes later in adolescence and emerging adulthood, as well as predicting work success in adulthood.
- ***What factors influence an individual child's vulnerability to suffering negative consequences as a result of living in a divorced family?*** Among the factors involved in the child's risk and vulnerability are the child's adjustment prior to the divorce, as well as the child's personality and temperament, and the custody situation (Hetherington, 2006). Children whose parents later divorce show



What concerns are involved in whether parents should stay together for the sake of the children or become divorced?

connecting development to life

Communicating with Children About Divorce

Ellen Galinsky and Judy David (1988) developed a number of guidelines for communicating with children about divorce:

- *Explain the separation*. As soon as daily activities in the home make it obvious that one parent is leaving, tell the children. If possible, both parents should be present when children are told about the separation to come. The reasons for the separation are very difficult for young children to understand. No matter what parents tell children, children can find reasons to argue against the separation. It is extremely important for parents to let the children know who will take care of them and to describe the specific arrangements for seeing the other parent.
- *Explain that the separation is not the child's fault*. Young children often believe their parents' separation or divorce is their own fault. Therefore, it is important to tell children that they are not the cause of the separation. Parents need to repeat this point a number of times.
- *Explain that it may take time to feel better*. Tell young children that it's normal not to feel good about what is happening and that many other children feel this way when their parents become separated. It is also okay for divorced parents to share some of their emotions with children by saying something like "I'm having a hard time since the separation just like you, but I know it's going to get better after a while." Such statements are best kept brief and should not criticize the other parent.
- *Keep the door open for further discussion*. Tell your children to come to you any time they want to talk about the separation. It is healthy for children to express their pent-up emotions in discussions with their parents and to learn that the parents are willing to listen to their feelings and fears.
- *Provide as much continuity as possible*. The less children's worlds are disrupted by the separation, the easier their transition to a single-parent family will be. This means maintaining the rules already in place as much as possible. Children need parents who care enough not only to give them warmth and nurturance but also to set reasonable limits.
- *Provide support for your children and yourself*. After a divorce or separation, parents are as important to children as they were before the divorce or separation. Divorced parents need to provide children with as much support as possible. Parents function best when other people are available to give them support as adults and as parents. Divorced parents can find people who provide practical help and with whom they can talk about their problems.

How well do these strategies complement E. Mavis Hetherington's six strategies for divorced adults, discussed earlier in this chapter?

poorer adjustment before the breakup (Amato & Booth, 1996). Children who are socially mature and responsible, who show few behavioral problems, and who have an easy temperament are better able to cope with their parents' divorce. Children with a difficult temperament often have problems coping with their parents' divorce (Hetherington, 2006). In one study, higher levels of predivorce maternal sensitivity and child IQ served as protective factors in reducing child problems after the divorce (Weaver & Schofield, 2015). Joint custody works best for children when the parents can get along with each other (Steinbach, 2019).

- ***What role does socioeconomic status play in the lives of children in divorced families?*** Custodial mothers experience the loss of about one-fourth to one-half of their predivorce income, in comparison with a loss of only one-tenth by custodial fathers (Emery, 1999). This income loss for divorced mothers is accompanied by increased workloads, high rates of job instability, and residential moves to less desirable neighborhoods with inferior schools (Braver & Lamb, 2013). One study found that children from families with higher incomes before the separation/divorce had fewer internalizing problems (Weaver & Schofield, 2015).

In sum, many factors affect how divorce influences a child's development (Lansford, 2019). To read about some strategies for helping children cope with the divorce of their parents, see the *Connecting Development to Life* interlude.

STEPFAMILIES

Not only are parents divorcing more, they are also getting remarried more (Jensen, 2020). The number of remarriages involving children has grown steadily in recent years. About half of all children whose parents divorce will have a stepparent within four years of parental separation.

However, divorces occur at a much higher rate in remarriages than in first marriages (DeLongis & Zwicker, 2017).

In some cases, the stepfamily may have been preceded by the death of the spouse. However, by far the largest number of stepfamilies are preceded by divorce rather than death.

Three common types of stepfamily structure are (1) stepfather, (2) stepmother, and (3) blended or complex. In stepfather families, the mother typically had custody of the children and remarried, introducing a stepfather into her children's lives. In stepmother families, the father usually had custody and remarried, introducing a stepmother into his children's lives. In a blended or complex stepfamily, both parents bring children from previous marriages to live in the newly formed stepfamily.

How does living in a stepfamily influence a child's development?
Todd Wright/Blend Images/Getty Images

In E. Mavis Hetherington's (2006) longitudinal analyses, children and adolescents who had been in a simple stepfamily (stepfather or stepmother) for a number of years were adjusting better than in the early years of the remarried family and were functioning well in comparison with children and adolescents in conflictual nondivorced families and children and adolescents in complex (blended) stepfamilies. More than 75 percent of the adolescents in long-established simple stepfamilies described their relationships with their stepparents as "close" or "very close." Hetherington (2006) concluded that in long-established simple stepfamilies, adolescents seem eventually to benefit from the presence of a stepparent and the resources provided by the stepparent.

Children often have better relationships with their custodial parents (mothers in stepfather families, fathers in stepmother families) than with stepparents (Santrock, Sitterle, & Warshak, 1988). Nonetheless, recent research indicates that the stepfather's affinity-seeking (developing a friendly relationship with his stepchild) is linked to less conflict with stepchildren, a better couple relationship, and closer stepfamily ties (Ganong & others, 2019, 2020). Also, children in simple stepfamilies (stepmother or stepfather) often show better adjustment than their counterparts in complex (blended) stepfamilies (Anderson & others, 1999; Hetherington & Kelly, 2002).

As in divorced families, children in stepfamilies show more adjustment problems than children in nondivorced families (Hetherington & Kelly, 2002). The adjustment problems are similar to those found among children of divorced parents—academic problems and lower self-esteem, for example (Anderson & others, 1999). As mentioned earlier, in one study 25 percent of children from divorced families showed adjustment problems compared with 10 percent in nondivorced families (Hetherington & Kelly, 2002). However, it is important to recognize that a majority of children in stepfamilies do not have problems. Further, a recent study found that when children have a supportive parent-child relationship with their stepparent, the children have fewer internalizing and externalizing problems (Jensen & others, 2018).

Adolescence is an especially difficult time in stepfamilies (Anderson & others, 1999). This difficulty may occur because becoming part of a stepfamily exacerbates normal adolescent concerns about identity, sexuality, and autonomy. In recent research, a positive relationship between adolescents and their stepfather was associated with higher levels of physical health and lower levels of mental health problems in adolescents (Jensen & Harris, 2017; Jensen & others, 2018).

LGBTQ FAMILIES

Increasingly, same-gender couples are creating families that include children (Farr & Vasquez, 2020a, b; Farr, Vasquez, & Patterson, 2020). Data indicate that approximately 20 percent of same-gender couples in the United States are raising children under the age of 18 (Gates, 2013). An important aspect of same-gender couples with children is the sexual orientation of parents at the time of a child's birth or adoption (Goldberg & Sweeney, 2019). The largest group of children with same-gender parents are likely those who were born in the context of different-gender relationships, with one or both parents later having a same-gender relationship.

What are some of the outcomes for children growing up with same-gender parents?
wavebreakmedia/Shutterstock

LGBTQ parents may be single or have same-gender partners. In addition, LGBTQ people are increasingly choosing parenthood through donor insemination or adoption. Researchers have found that the children created through new reproductive technologies—such as in vitro fertilization—are as well-adjusted as their counterparts conceived by natural means (Golombok, 2011a, b).

Another issue focuses on custody arrangements for adolescents. Many LGBTQ people have lost custody of their adolescents to different-gender spouses following divorce. For this reason, many LGBTQ parents are noncustodial parents.

Research by Rachel Farr and her colleagues (2020) have found few differences between children growing up with same-gender parents and children growing up with different-gender parents. For example, children growing up with same-gender parents are just as popular with their peers, and there are no differences between the adjustment and mental health of children living in these families and children living with different-gender parents (Hyde & DeLamater, 2020). For example, in a recent study, the adjustment of school-aged children adopted during infancy by same- and different-gender parents showed no differences (Farr, 2017). Rather, children's behavior patterns and family functioning were predicted by earlier child adjustment issues and parental stress. Further, a UK longitudinal study that assessed gay father, lesbian mother, and heterosexual parent families when their adopted children reached early adolescence found little difference between the three family types, but better parenting quality and parental mental health were linked to fewer adolescent problems (McConnachie & others, 2021). Also, the overwhelming majority of children growing up with same-gender parents have a heterosexual orientation (Golombok & Tasker, 2010).

One study compared the incidence of coparenting in adoptive same-gender and different-gender couples with preschool-aged children (Farr & Patterson, 2013). Both self-reports and observations found that same-gender couples shared child care more than different couples did, with same-gender women couples being the most supportive and same-gender men couples the least supportive. Also, in a recent study, lesbian mothers, heterosexual mothers, and gay fathers reported higher parenting competence than heterosexual fathers (Farr & Vasquez, 2020a).

ADOPTIVE PARENTS AND ADOPTED CHILDREN

Another variation in the type of family in which children live involves adoption, the social and legal process by which a parent-child relationship is established between persons unrelated at birth. As we see next, many aspects of adoptive families in the United States have changed in recent years.

The Increased Diversity of Adopted Children and Adoptive Parents A number of changes have characterized adopted children and adoptive parents in the last three to four decades (Farr & Grotevant, 2019; Pinderhughes & Brodzinsky, 2019). In the first half of the twentieth century, most U.S. adopted children were healthy, non-Latinx White infants who were adopted at birth or soon after; however, in recent decades as abortion became legal and use of contraception increased, fewer of these infants became available for adoption. Increasingly, U.S. couples have adopted a much wider diversity of children—from other countries, from other ethnic groups, children with physical and/or mental problems, and children who had been neglected or abused (Friedman & Lynch, 2020).

Changes also have characterized adoptive parents in the last three to four decades (Brodzinsky & Pinderhughes, 2002). In the first half of the twentieth century, most adoptive parents were heterosexuals from non-Latinx White middle- or upper-socioeconomic-status backgrounds who were married and did not have any type of disability. However, in recent decades, increased diversity has characterized adoptive parents. Many adoption agencies today have no income requirements for adoptive parents and now allow adults from a wide range of backgrounds to adopt children, including single adults, LGBTQ adults, and older adults (Farr, 2017; Farr & others, 2016; McConnachie & others, 2020). Further, many adoptions involve other family members (such as aunts, uncles, or grandparents); currently, 30 percent of U.S. adoptive placements are with relatives (Ledesma, 2012). And slightly more than 50 percent of U.S. adoptions occur through the foster care system; in 2014, almost 110,000 children in the U.S. foster care system were waiting for someone to adopt them. Three pathways to adoption are (1) domestic adoption from the public welfare system, (2) domestic infant adoption through private agencies and intermediaries, and (3) international

What Role Might School Counselors Play in Transracial Adoption?

Courtesy Dr. Susan Branco

Susan Branco

Key Points:

- transracial adoption
- elementary school counselors
- identity development

Dr. Susan Branco's (2021) research interests include exploring how school and mental health counselors interact with individuals who have been adopted transracially. While research has focused primarily on parents and teachers, in many cases school counselors are the among the first to be involved when concerns arise involving students adopted transracially.

In one study, school counselors indicated they had not received specific training in adoption-sensitive counseling practices; thus, they relied on their current competencies as they developed necessary skills and acquired needed information (Branco & Brott, 2017). Analysis of the interviews revealed one primary, all-encompassing theme. The elementary school counselors guided their efforts by continually asking themselves, "Am I confident in, and comfortable with, the services I am providing?" Among the challenges faced by the counselors were uninformed parents who had poor pre-adoptive training and little understanding of cultural differences. The counselors also felt challenged by complex identity development of the students adopted transracially and the need to become advocates for both them and social justice issues.

In addition to teachers and school counselors, who else might parents turn to for advice and accurate information when parenting an adopted child of a different race or ethnicity?

adoption. In the next decade, the mix of U.S. adoptions is likely to include fewer domestic infant and international adoptions and more adoptions via the child welfare system (Farr & Hrapczynski, 2020).

Parents who adopt a child of a different racial or ethnic background may find they need specialized information, such as ways to blend cultures in their home or facilitate the identity development of their transracially adopted child. To learn more about the role of elementary school counselors in assisting transracial adoptive families, see the *Connecting with Research* interlude.

The changes in adoption practice over the last several decades make it difficult to generalize about the average adopted child or average adoptive parent (Woolgar & Scott, 2013). As we see next, though, some researchers have provided useful comparisons between adopted children and nonadopted children and their families.

Developmental Outcomes for Adopted and Nonadopted Children How do adopted children fare after they are adopted? A research review concluded that adopted children are at higher risk than nonadopted children for externalizing (aggression and conduct problems, for example), internalizing (anxiety and depression, for example), and attention problems (ADHD, for example) (Grotevant & McDermott, 2014). A review of research involving internationally adopted adolescents concluded that the adoptees had a higher level of mental health problems than their nonadopted counterparts (Askeland & others, 2017). Nevertheless, the majority of adopted children and adolescents (including those adopted at older ages, transracially, and across national borders) adjust effectively, and their parents report considerable satisfaction with their decision to adopt (Castle & others, 2010).

An ongoing issue in adopting children is whether to maintain a connection with children's biological parents (Leve, Harold, & Kintner, 2020). Open adoption involves sharing identifying information and having contact with the biological parents, while closed adoption involves no sharing or contact. Most adoption agencies today offer adoptive parents the opportunity to have either an open or a closed adoption. A longitudinal study found that when their adopted children reached adulthood, adoptive parents described open adoption positively and saw it as serving the child's best interests (Siegel, 2013). Another longitudinal study found that birth

What are some strategies for parenting adopted children at different points in their development?
Photodisc/Getty Images

mothers, adoptive parents, and birth children who had contact were more satisfied with their arrangements than those who did not have contact (Grotevant & others, 2013). Also, in this study, contact was linked to more optimal adjustment for adolescents and emerging adults (Grotevant & others, 2013). Birth fathers are often less likely to be included in open adoption, but a recent study indicated that they would like be part of the open adoption triad (adoptee, birth family, and adoptive family) (Clutter, 2020).

Parenting Adopted Children Many of the keys to effectively parenting adopted children are no different from those for effectively parenting biological children: be supportive and caring; be involved and monitor the child's behavior and whereabouts; be a good communicator; and help the child learn to develop self-control. However, parents of adopted children face some unique circumstances. They need to recognize the differences involved in adoptive family life, communicate about these differences, show respect for the birth family, and support the child's search for self and identity.

Because many children begin to ask where they came from when they are about 4 to 6 years old, this is a natural time for parents to begin talking in simple ways to children about their adoption status (Warshak, 2017). Some parents (although not as many as in the past) decide not to tell their children about the adoption. This secrecy may create psychological risks for the child if he or she later finds out about the adoption.

4 Other Family Relationships

LG4 Explain other aspects of family relationships.

Sibling Relationships and Birth Order

Grandparenting and Great-Grandparenting

Intergenerational Relationships

As important as child-parent relationships are to children's development, other family relationships are also important. Here we briefly examine sibling relationships, grandparenting and great-grandparenting, and intergenerational relationships.

SIBLING RELATIONSHIPS AND BIRTH ORDER

What are sibling relationships like? How extensively does birth order influence behavior?

Sibling Relationships Approximately 80 percent of American children have one or more siblings—that is, sisters and brothers (Dunn, 2015). If you grew up with siblings, you probably have abundant memories of aggressive, hostile interchanges. Siblings in the presence of each other when they are 2 to 4 years of age, on average, have a conflict once every 10 minutes, and then the conflicts decrease somewhat from 5 to 7 years of age (Kramer, 2006). What do parents do when they encounter siblings having a verbal or physical confrontation? One study revealed that they do one of three things: (1) intervene and try to help them resolve the conflict, (2) admonish or threaten them, or (3) do nothing at all (Kramer & Perozynski, 1999). Of interest is that in families with two siblings 2 to 5 years of age, the most frequent parental reaction is to do nothing at all. A research review concluded that sibling relationships in adolescence are more egalitarian and not as close or as intense as sibling relationships during childhood (East, 2009). Indeed, beginning in adolescence, sibling companionship begins to decline in many cultures as boys and girls become increasingly involved in the world beyond their family (McHale, Updegraff, & Whiteman, 2013).

Negative aspects of sibling relationships, such as high conflict, are linked to negative outcomes for children and adolescents (Kramer & others, 2019). The negative outcomes can develop not only through conflict but also through direct modeling of a sibling's behavior, as when a younger sibling has an older sibling who has poor study habits and engages in delinquent behavior. By contrast, close and supportive sibling relationships can buffer the negative effects of stressful circumstances in children's and adolescents' lives (Kramer & others, 2019).

However, conflict is only one of the many dimensions of sibling relations (Salmivalli, 2020). Sibling relationships include helping, sharing, teaching, fighting, and playing, and siblings can act as emotional supports, rivals, and communication partners.

Judy Dunn (2007, 2015), a leading expert on sibling relationships, described three important characteristics of sibling relationships:

- *Emotional quality of the relationship.* Intense positive and negative emotions are often expressed by siblings toward each other. Many children and adolescents have mixed feelings toward their siblings.
- *Familiarity and intimacy of the relationship.* Siblings typically know each other very well, and this intimacy suggests that they can either provide support or tease and undermine each other, depending on the situation.
- *Variation of the relationship.* Some siblings describe their relationships more positively than others. Thus, there is considerable variation in sibling relationships. We have indicated that many siblings have mixed feelings about each other, but some children and adolescents mainly describe their sibling in warm, affectionate ways, whereas others primarily talk about how irritating and mean a sibling is.

What characterizes children's sibling relationships?
(*Top*): RubberBall Productions/Getty Images; (*bottom*): RubberBall Productions/Photodisc/Getty Images

Do parents usually favor one sibling over others—and if so, does it make a difference in an adolescent's development? One study of 384 adolescent sibling pairs revealed that 65 percent of their mothers and 70 percent of their fathers showed favoritism toward one sibling (Shebloski, Conger, & Widaman, 2005). When favoritism of one sibling occurred, it was linked to lower self-esteem and sadness in the less-favored sibling. Indeed, equality and fairness are major concerns in siblings' relationships with each other and how they are treated by their parents (Aldercotte, White, & Hughes, 2016; Campione-Barr, Greer, & Kruse, 2013).

In some instances, siblings may be stronger socializing influences on the child than parents are. Someone close in age to the child—such as a sibling—may be able to understand the child's

A one-child policy has been in place for a number of decades in China. However, in 2016, the Chinese government began allowing two children per family without a financial penalty. *In general, though, what have researchers found the only child to be like?*
Image Source/Getty Images

problems and communicate more effectively than parents can. In dealing with peers, coping with difficult teachers, and discussing taboo subjects such as sex, siblings may have more influence than parents.

Birth Order Whether a child has older or younger siblings has been linked to development of certain personality characteristics. For example, one review concluded that "firstborns are the most intelligent, achieving, and conscientious, while later-borns are the most rebellious, liberal, and agreeable" (Paulhus, 2008, p. 210). Compared with later-born children, firstborn children have also been described as more adult-oriented, helpful, conforming, and self-controlled. However, when such birth-order differences are reported, they often are small.

What might account for even small differences related to birth order? Proposed explanations usually point to variations in interactions with parents and siblings associated with being in a specific position in the family (Feinberg, McHale, & Whiteman, 2019). This is especially true in the case of the firstborn child (Teti, 2001). The oldest child is the only one who does not have to share parental love and affection with other siblings—until a sibling comes along. An infant requires more attention than an older child; thus, the firstborn sibling receives less attention after the newborn arrives. Does this result in conflict between parents and the firstborn? In one research study, mothers became more negative, coercive, and restraining and played less with the firstborn following the birth of a second child (Dunn & Kendrick, 1982).

What is the only child like? The popular conception is that the only child is a "spoiled brat" with undesirable characteristics such as dependency, lack of self-control, and self-centered behavior. But researchers present a more positive portrayal of the only child. Only children often are achievement-oriented and display a desirable personality, especially in comparison with later-borns and children from large families (Falbo & Poston, 1993).

So far, our discussion suggests that birth order might be a strong predictor of behavior. However, an increasing number of family researchers stress that when all of the factors that influence behavior are considered, birth order by itself shows limited ability to predict behavior. In a recent large-scale study, a birth order effect occurred for intelligence, with firstborns having slightly higher intelligence; however, there were no birth order effects for life satisfaction, internal/external control, trust, risk taking, patience, and impulsivity (Rohrer, Egloff, & Schmukle, 2017).

Think about some of the other important factors in children's lives beyond birth order that influence their behavior. They include heredity, models of competency or incompetency that parents present to children on a daily basis, peer influences, school influences, socioeconomic factors, sociohistorical factors, and cultural variations. When someone says firstborns are always like this but last-borns are always like that, the person is making overly simplistic statements that do not adequately take into account the complexity of influences on a child's development.

Sibling Relationships in Adulthood Sibling relationships persist over the entire life span for most adults. Eighty-five percent of today's adults have at least one living sibling. Sibling relationships in adulthood may be extremely close, apathetic, or highly rivalrous, but the majority of sibling relationships in adulthood have been found to be close (Cicirelli, 2009). Those siblings who are psychologically close to each other in adulthood tended to be that way in childhood. It is rare for sibling closeness to develop for the first time in adulthood (Dunn, 1984).

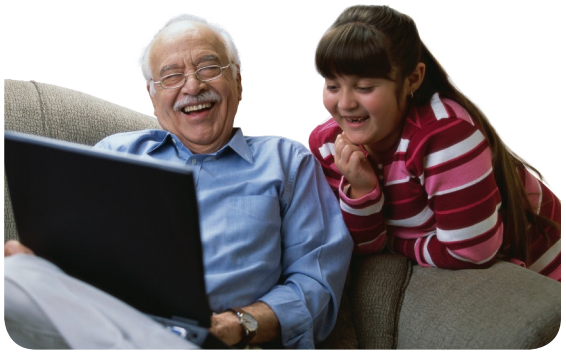
GRANDPARENTING AND GREAT-GRANDPARENTING

Increased longevity is changing the nature of grandparenting (Smith & Wild, 2019). As more people live to older ages, increasing numbers of grandparents can be part of their grandchildren's lives. From 2001 to 2017, the number of grandparents in the United States grew by 24 percent—from 56 million to 70 million (AARP, 2019).

How might U.S. grandparents compare with their counterparts in other countries? In a recent cross-cultural comparison, U.S. grandparents were characterized by higher parental efficacy, more role satisfaction, better well-being, and more attachment than Chinese grandparents, who were characterized by better resilience and more authoritative parenting (Wang & others, 2019).

Grandparent Roles Grandparents play important roles in the lives of many grandchildren (Condon, Luszcz, & McKee, 2020). Many adults become grandparents for the first time during middle age. Researchers have consistently found that grandmothers have more contact with grandchildren than do grandfathers (Watson, Randolph, & Lyons, 2005). Perhaps women tend to define their role as grandmothers as part of their responsibility for maintaining ties between family members across generations. Men may have fewer expectations about the grandfather role and see it as more voluntary.

Three prominent meanings are attached to being a grandparent (Neugarten & Weinstein, 1964). For some older adults, being a grandparent is a source of biological reward and continuity. For others, being a grandparent brings emotional fulfillment, generating feelings of companionship and satisfaction that may have been missing in earlier adult-child relationships. And for yet others, being a grandparent is a remote role.



What is the changing profile of grandparents in the United States?
Dex Images/Getty Images

The Changing Profile of Grandparents In 2014, 10 percent of U.S. children (7.4 million) lived with at least one grandparent, a dramatic increase since 1981 when 4.7 million children were living with at least one grandparent (U.S. Census Bureau, 2015). Divorce, adolescent pregnancies, and drug use by parents are the main reasons that grandparents are thrust back into the "parenting" role they thought they had shed. A recent study found that when children live with grandparents this arrangement especially benefits low-income and single parents, who are able to invest more money in their children's education and activities than they could spend if they had to pay for child care (Amorim, 2019).

Grandparents who are full-time caregivers for grandchildren are at elevated risk for health problems, depression, and stress (Silverstein, 2009). A research review concluded that grandparents raising grandchildren are especially at risk for developing depression (Hadfield, 2014). However, a recent Japanese study found that caring for at least one co-residing grandchild age 6 years or younger was neither detrimental nor beneficial to the grandparents' health (Oshio, 2021).

As divorce and remarriage have become more common, a special concern of grandparents is visitation privileges with their grandchildren. In the last 10 to 15 years, more states have passed laws giving grandparents the right to petition a court for visitation privileges with their grandchildren, even if a parent objects. Whether such forced visitation rights for grandparents are in the child's best interest is still being debated.

At the beginning of the twentieth century, the three-generation family was common, but now the four-generation family is common as well. Thus, an increasing number of grandparents are also great-grandparents. The four-generation family shown here is the Jordans—author John Santrock's mother-in-law, daughter, granddaughter, and wife.
Courtesy of Dr. John Santrock

Great-Grandparenting Because of increased longevity, more grandparents today than in the past are also great-grandparents. At the turn of the previous century, the three-generation family was common, but now the four-generation family is common. It is estimated that by 2030, more than 70 percent of 8-year-olds in the United States will have at least one great-grandparent who is living (AARP, 2019). One contribution of great-grandparents is to transmit family history by telling their children, grandchildren, and great-grandchildren where the family came from, what their members achieved, what they endured, and how their lives changed over the years (Harris, 2002).

There has been little research on great-grandparenting. One study examined the relationship between young adults and their grandparents and great-grandparents (Roberto & Skoglund, 1996). The young adults interacted with and participated in more activities with their grandparents than with their great-grandparents. They also perceived their grandparents to have a more defined role and to be more influential in their lives than great-grandparents.

INTERGENERATIONAL RELATIONSHIPS

Family is important to most people (Steinbach & others, 2021). When 21,000 adults aged 40 to 79 in 21 countries were asked, "When you think of who you are, you think mainly of . . .", 63 percent said "family," 9 percent said "religion," and 8 percent said "work" (HSBC Insurance, 2007). In this study, in all 21 countries, middle-aged and older adults expressed a strong feeling of responsibility between generations in their family, with the strongest intergenerational ties indicated in Saudi Arabia, India, and Turkey. More than 80 percent of these middle-aged and older adults stated that adults have a duty to care for their parents (and parents-in-law) in time of need later in life.

The generations of living things pass in a short time, and like runners hand on the torch of life.

Roman Poet, 1st Century B.C.

Middle-aged and older adults around the world show a strong sense of family responsibility. A recent study of middle-aged and older adults in 21 countries revealed that the strongest intergenerational ties were in Saudi Arabia.
Reza/National Geographic/Getty Images

The Empty Nest and Its Refilling An important event in a family is the launching of a child into adult life. Parents face new adjustments as a result of the child's absence. College students usually think that their parents suffer from their absence. In fact, parents who live vicariously through their children might experience the **empty nest syndrome,** which includes a decline in marital satisfaction after children leave the home. For most parents, however, marital satisfaction does not decline after children have left home. Rather, for most parents marital satisfaction increases during the years after child rearing (Fingerman & Baker, 2006). With their children gone, marital partners have time to pursue careers and other interests and more time for each other. One study revealed that the transition to an empty nest increased marital satisfaction and that this increase was linked to an increase in the quality of time—but not the quantity of time—spent with partners (Gorchoff, John, & Helson, 2008).

The middle generation has always provided support for the younger generation, even after the nest is bare. Through loans and monetary gifts for education, and through emotional support, the middle generation has helped the younger generation. Adult children appreciate the financial and emotional support their parents provide them at a time when they often feel considerable stress about their career, work, and lifestyle. And parents feel good that they can provide this support.

In today's uncertain economic climate, the refilling of the empty nest is becoming a common occurrence as adult children return to their parents' home after several years of college, after graduating from college, or to save money after taking a full-time job (Fingerman & others, 2012a). Young adults also may move back in with their parents after an unsuccessful career or a divorce. And some individuals don't leave home at all until their middle to late twenties because they cannot financially support themselves. Numerous labels have been applied to these young adults who return to their parents' homes to live, including "boomerang kids" and "B2B" (or Back-to-Bedroom) (Furman, 2005).

As with most family living arrangements, there are both pluses and minuses when adult children live with their parents (Fingerman & others, 2016). One of the most common complaints voiced by both adult children and their parents is a loss of privacy. The adult children complain that their parents restrict their independence, cramp their sex lives, reduce their music listening, and treat them as children rather than adults. Parents often complain that their quiet home has become noisy, that they stay up late worrying about when their adult children will come home, that meals are difficult to plan because of conflicting schedules, that their relationship as a married or partnered couple has been invaded, and that they have to shoulder too much responsibility for their adult children. In sum, when adult children return home to live, the changes in family life require considerable adaptation on the part of parents and their adult children.

What are some strategies that can help parents and their young adult children get along better?
Fuse/Getty Images

When adult children ask to return home to live, parents and their adult children should agree on the conditions and expectations beforehand. For example, they might discuss and agree on whether young adults will pay rent, wash their own clothes, cook their own meals, do any household chores, pay their phone bills, come and go as they please, be sexually active or drink alcohol at home, and so on. If these conditions aren't negotiated at the beginning, conflict often results because the expectations of parents and young adult children will likely be violated.

Research indicates that today's parents and their emerging adult/young adult children have more contact with each other than did earlier generations, with the connections especially strengthening during the first decade of the twenty-first century (Fingerman, 2012b). Keeping in touch has become easier with advances in technology, and today's emerging and young adults frequently text their parents and become friends with their parents on Facebook. Recent research indicates that today's emerging adults and young adults appreciate their parents' emotional and financial support. Nonetheless, there is concern when this parental support becomes too intense, in which case it can restrict emerging and young adults' development of autonomy (Fingerman, 2012b). The term "helicopter parents" has been applied to this type of support (Weitkamp

empty nest syndrome View that a decline in marital satisfaction occurs when children leave home; however, research indicates that for most parents there is an upswing in marital satisfaction when children are launched into adult life.

& Seiffge-Krenke, 2019). In a recent study, high levels of parental control and helicopter parenting were detrimental to emerging adults' vocational identity development and perceived competence in transitioning to adulthood (Lindell, Campione-Barr, & Killoren, 2017). And in another recent study, helicopter parenting was related to more negative emotional functioning, less competent decision making, and lower grades/poorer adjustment in college-age adults (Luebbe & others, 2018).

Recently, a new term that characterizes a number of parents today is "lawn mower parent"—a parent who goes to great lengths to prevent their child from experiencing adversity, stress, or failure. By "mowing down" obstacles and potential negative experiences for their children, these parents are not allowing their children to learn how to cope with such experiences themselves. When their children have to face these struggles on their own as they leave home and go to college or enter a career, they are less likely to handle the pressure and challenges as well as they would have if their parents had provided them more space to make decisions and learn how to cope on their own.

What is the nature of intergenerational relationships?
Steve Casimiro/The Image Bank/Getty Images

As discussed in the next section, a considerable degree of ambivalence characterizes intergenerational relationships in many families, with middle-aged adults playing a key role in connecting generations.

The Midlife Generation Adults in midlife play important roles in the lives of the young and the old (Wang & others, 2020). Middle-aged adults share their experience and transmit values to the younger generation. They may be launching children and experiencing the empty nest, adjusting to having grown children return home, or becoming grandparents. They also may be giving or receiving financial assistance, caring for a widowed or sick parent, or adapting to being the oldest generation after both parents have died. A recent study indicated that middle-aged adults are happiest when they have harmonious relationships with their parents and their grown children (Kim & others, 2020).

Middle-aged adults have been described as the "sandwich," "squeezed," or "overload" generation because of the responsibilities they have for their adolescent and young adult children on the one hand and their aging parents on the other (Etaugh & Bridges, 2010). However, Karen Fingerman and her colleagues (Fingerman, Zarit, & Birditt, 2019; Fingerman & others, 2018) offer an alternative view, concluding that in the United States, a "sandwich" generation, in which the middle generation cares for both grown children and aging parents simultaneously, occurs less often than a "pivot" generation, in which the middle generation alternates attention between the demands of grown children and aging parents.

Many middle-aged adults experience considerable stress when their parents become very ill and die (Zarit & others, 2019). One survey found that when adults enter midlife, 41 percent have both parents alive, but that 77 percent leave midlife with no parents alive (Bumpass & Aquilino, 1994). By middle age, more than 40 percent of adult children (most of them daughters) provide care for aging parents or parents-in-law (Blieszner & Roberto, 2012). However, researchers have found that middle-aged parents are more likely to provide support to their grown children than to their parents (Fingerman & others, 2011).

In most cases researchers have found that relationships between aging parents and their children are characterized by ambivalence (Fingerman, Zarit, & Birditt, 2019). Perceptions include love, reciprocal help, and shared values on the positive side and isolation, family conflicts and problems, abuse, neglect, and caregiver stress on the negative side. One study found that middle-aged adults positively supported family responsibility to emerging adult children but were more ambivalent about providing care for aging parents, viewing it as both a joy and a burden (Igarashi & others, 2013).

With each new generation, personality characteristics, attitudes, and values are replicated or changed. As older family members die, their biological, intellectual, emotional, and personal legacies are carried on in the next generation. Their children become the oldest generation and their grandchildren the second generation. Both similarity and dissimilarity across generations are found. For example, similarity between parents and an adult child is most noticeable in religion and politics, and less apparemt in gender roles, lifestyle, and work orientation.

Gender Gender differences also characterize intergenerational relationships (Pei, Cong, & Wu, 2020). Women have an especially important role in maintaining family relationships across generations. Women's relationships across generations are typically closer than other family bonds (Merrill, 2009). In one study, mothers and their daughters had much closer relationships during their adult years than mothers and sons, fathers and daughters, and fathers and sons (Rossi, 1989). Also in this study, married men were more involved with their wives' kin than with their own. And maternal grandmothers and maternal aunts were cited twice as often as their counterparts on the paternal side of the family as the most important or loved relative.

Review *Connect* Reflect

LG4 Explain other aspects of family relationships.

Review

- How do siblings interact with each other? How is birth order linked with developmental outcomes?
- What is the nature of grandparenting and great-grandparenting?
- How do intergenerational relationships influence development?

Connect

- Connect what you have learned about longevity to this chapter's discussion of grandparenting and great-grandparenting.

Reflect *Your Own Personal Journey of Life*

- Do you have a sibling? If so, what is your relationship like? Has it changed over the years? If you don't have a sibling, how do you think your life would have been different with one or more siblings?

Families, Relationships, and Parenting

1 Family Processes

LG1 Describe some important family processes.

Reciprocal Socialization

- Reciprocal socialization is socialization that is bidirectional; children socialize parents just as parents socialize children. Synchrony and scaffolding are two important types of reciprocal socialization.

Family as a System

- The family system consists of subsystems defined by generation, gender, and role. These subsystems interact with each other and can have direct and indirect effects on each other.

Sociocultural and Historical Influences

- Sociocultural and historical contexts influence families, reflecting Bronfenbrenner's concepts of macrosystem and chronosystem. Both great upheavals such as war and subtle transitions in ways of life may influence families. A major change in families in the last several decades has been the extensive immigration of Latinx and Asian families into the United States.

2 The Diversity of Adult Relationships and Families

LG2 Discuss the diversity of adult relationships and families and how they influence people's lives.

Single Adults

- Being single has become an increasingly prominent adult relationship. There are advantages and disadvantages to being single, with autonomy being one of the advantages. Intimacy, loneliness, and finding a positive identity in a marriage-oriented society are concerns of single adults. Approximately 8 percent of 65-year-old adults have never been married. Many of them cope effectively with loneliness in old age.

Cohabiting Adults

- Cohabitation is an increasingly prevalent relationship for many adults that offers some advantages as well as problems. Cohabitation does not lead to greater marital happiness but rather to no differences or to differences suggesting that it is not good for a marriage. An increasing number of older adults cohabit, in many cases more for companionship than for love.

Married Adults

- Even though adults are remaining single longer and the divorce rate is high, Americans still show a strong predilection for marriage. The age at which individuals marry, expectations about what the marriage will be like, and the developmental course of marriage vary not only over time within a culture but also across cultures.
- John Gottman has conducted extensive research on what makes marriages work. In his research, the following factors are among the most important for having a good marriage: establishing love maps, nurturing fondness and admiration, turning toward each other instead of away, letting your partner influence you, overcoming gridlock, and creating shared meaning.
- Premarital education is associated with positive relationship outcomes. The benefits of marriage include better physical and mental health and a longer life. A majority of middle-aged adults who are married say their marriage is very good or excellent. The time from retirement until death is sometimes called the final stage in the marital process. Married older adults are often happier than single older adults.

Divorced Adults

- The U.S. divorce rate increased dramatically in the twentieth century but began to decline in the 1980s. Divorce is complex and emotional. In the first year following divorce, a disequilibrium in the divorced adult's behavior occurs, but several years after the divorce, more stability usually is achieved. A divorced displaced homemaker may encounter excessive stress; however, men do not go through a divorce unscathed. There are social, financial, and physical consequences of divorce for older adults.

Remarried Adults

- Divorced adults remarry on average within four years of their divorce. Stepfamilies are complex and adjustment is difficult. Only about one-third of stepfamily couples stay remarried. Rising divorce rates, increased longevity, and better health have led to increased rates of remarriage among older adults.

LGBTQ Adults

- One of the most striking findings about same-gender couples is how similar they are to different-gender couples—for example, same-gender couples prefer committed, long-term relationships and work to find a balance of romantic love, affection, and autonomy. There are many misconceptions about LGBTQ adults.

3 Parenting

LG3 Characterize parenting and how it affects children's development.

Parental Roles

- Currently, there is a trend toward having fewer children and choosing when to have children. The transition to parenting involves a great deal of adaptation for many people. A key aspect of being a competent parent is effectively managing children's lives and understanding adolescents' information management.

Parenting Styles and Discipline

- Authoritarian, authoritative, neglectful, and indulgent are four main parenting styles. Authoritative parenting is the style most often associated with children's social competence. Physical punishment is widely used by U.S. parents, but there are a number of reasons why it is not a good choice.
- Coparenting can have positive effects on children's development if it is accompanied by parental warmth and cooperation.
- The four main types of child maltreatment are physical abuse, child neglect, sexual abuse, and emotional abuse. An understanding of child abuse requires information about cultural, familial, and community influences. Child maltreatment places the child at risk for a number of developmental problems.

Parent-Adolescent and Parent-Emerging Adult Relationships

- Adolescents seek to be independent, but secure attachment to parents is a positive influence on development. Conflict with parents often increases in adolescence but usually is moderate rather than severe. An increasing number of emerging adults are returning home to live with their parents, often for economic reasons. Both emerging adults and their parents need to adapt when emerging adults return home to live.

Working Parents

- In general, having both parents employed full-time outside the home has not been shown to have negative effects on children. However, the nature of parents' work can affect the quality of their parenting.

Children in Divorced Families

- Overall, divorce is linked with adjustment problems in children, but not for all children. Whether parents should stay together for the sake of the children is a difficult question to answer. Family processes, such as harmony between parents, quality of parenting, and support systems, matter in the development of children of divorced parents. So does socioeconomic status.

Stepfamilies

- Children in stepparent families have more problems than their counterparts in nondivorced families. Adolescence is an especially difficult time for remarriage of parents to occur. Restabilization takes longer in stepfamilies than in divorced families.

LGBTQ Families

- Researchers have found few differences between children growing up with same-gender parents and children growing up with different-gender parents.

Adoptive Parents and Adopted Children

- Although adopted children and adolescents have more problems than their nonadopted counterparts, the vast majority of adopted children adapt effectively. When adoption occurs very early in development, the outcomes for the child are improved. Because of the dramatic changes that have occurred in adoption in recent decades, it is difficult to generalize about characteristics of the average adopted child or average adoptive family.

4 Other Family Relationships

LG4 Explain other aspects of family relationships.

Sibling Relationships and Birth Order

- Siblings interact with each other in positive and negative ways. Birth order is related in certain ways to child characteristics, but some critics argue that birth order is not a good predictor of behavior. Sibling relationships persist over the entire life span for most adults.

Grandparenting and Great-Grandparenting

- There are different grandparent roles and styles. Grandmothers spend more time with grandchildren than grandfathers do, and the grandmother role involves greater expectations for maintaining ties across generations than the grandfather role. The profile of grandparents is changing because of factors such as divorce and remarriage. An increasing number of U.S. grandchildren live with their grandparents. Because of increased longevity, more grandparents today are also great-grandparents. One contribution of great-grandparents is their knowledge of family history.

Intergenerational Relationships

- For most families, there is an upswing in marital satisfaction when children are launched into adulthood. Family members usually maintain contact across generations. Mothers and daughters have the closest relationships. The middle-aged generation plays an important role in linking generations. In many families, ambivalence characterizes intergenerational relationships.

PEERS AND THE SOCIOCULTURAL WORLD

chapter **outline**

1 Peer Relations in Childhood and Adolescence

Learning Goal 1 Discuss peer relations in childhood and adolescence.

Exploring Peer Relations
Peer Statuses
Bullying
Gender and Peer Relations
Adolescent Peer Relations

2 Friendship

Learning Goal 2 Explain the role of friendship through the life span.

Functions of Friendship
Friendship During Childhood
Friendship During Adolescence and Emerging Adulthood
Friendship During Adulthood

3 Play and Leisure

Learning Goal 3 Describe the developmental aspects of play and leisure.

Childhood
Adolescence
Adulthood

4 Aging and the Social World

Learning Goal 4 Summarize the social aspects of aging.

Social Theories of Aging
Stereotyping of Older Adults
Social Support and Social Integration
Successful Aging

5 Sociocultural Influences

Learning Goal 5 Evaluate sociocultural influences on development.

Culture
Socioeconomic Status and Poverty
Ethnicity

preview

The social worlds outside the family play important roles in life-span development. As we go through life, we interact with a convoy of people through peer relations, friendships, cliques, and support systems in many different cultural worlds.

1 Peer Relations in Childhood and Adolescence

LG1 Discuss peer relations in childhood and adolescence.

- Exploring Peer Relations
- Peer Statuses
- Bullying
- Gender and Peer Relations
- Adolescent Peer Relations

As children grow older, peer relations consume increasing amounts of their time. In some cases these relations are positive influences, in others negative.

EXPLORING PEER RELATIONS

Peer relations influence people's lives from childhood through late adulthood, raising important questions like these: What are the functions of a child's peer group? How are peer relations and adult-child relations linked? What are some developmental changes in peer relations during childhood? What role does social cognition play in peer relations? How is emotion regulation involved in peer relations?

Functions of Peer Groups

Peers are individuals of about the same age or maturity level. Peer groups provide a basis for comparison as well as information about the world outside the family (Graham, 2020). Children receive feedback about their abilities from their peer group. They evaluate what they can do in terms of whether it is better than, as good as, or worse than what other children do. It is hard to make such comparisons at home because siblings are usually older or younger.

Researchers have found that children's peer relations can have long-term consequences (Hay, 2020). For example, one study indicated that low peer status in childhood (low acceptance/likeability) was linked to increased probability of being unemployed and having mental health problems in adulthood (Almquist & Brannstrom, 2014).

Both Jean Piaget (1932) and Harry Stack Sullivan (1953) stressed that children learn reciprocity through interaction with their peers. Children explore the meanings of fairness and justice by working through disagreements with peers. They also learn to be keen observers of peers' interests and perspectives in order to smoothly integrate themselves into ongoing peer activities. Susceptibility to peer influences can have positive or negative consequences (Salmivalli, 2020). For example, in one study, children who associated with peers who engaged in prosocial behavior at age 9 had a higher level of self-control at age 10, and those who associated with peers who engaged in deviant behavior at age 9 had a lower level of self-control at age 10 (Meldrum & Hay, 2012). Also, a recent study that examined parent and peer influences on adolescents' smoking revealed that peers had a more powerful influence than parents did (Scalici & Schulz, 2017).

What are some functions of a peer group?
Shutterstock

peers Individuals who share the same age or maturity level.

Being rejected or overlooked by peers leads some children to feel lonely or hostile. Further, rejection and neglect by peers are related to an individual's subsequent mental health difficulties and criminal problems. Withdrawn children who are rejected or victimized by their peers are at risk for depression (Jacobs & others, 2020). Children who are aggressive with their peers are at risk for a number of adverse outcomes, including conduct problems, delinquency, and dropping out of school (Shi & others, 2020). Peers can also undermine parental values and control (Vitoria & others, 2020).

Keep in mind that the influences of peer experiences vary according to the type of peer experience, developmental status, and outcome (such as achievement, delinquency, depression,

and so on) (Prinstein & Giletta, 2020). "Peers" and "peer group" are global concepts. For example, "peer group" might refer to acquaintances, members of a clique, neighborhood associates, a friendship network, or an activity group.

Adult-Child and Peer Relations Parents may influence their children's peer relations in many ways, both direct and indirect (Krisnana & others, 2021). Parents affect their children's peer relations through their interactions with their children, how they manage their children's lives, and the opportunities they provide to their children.

Basic lifestyle decisions by parents—their choices of neighborhoods, churches, schools, and their own friends—largely determine the pool from which their children select possible friends. These choices in turn affect which children their own children meet, their purpose in interacting, and eventually which children become their friends.

Children and adolescents live in a connected world that includes both parents and peers, not one in which parents and peers are disconnected from each other (Kaufman & others, 2020). In recent research with third- and fourth-graders, feeling related to peers at school was associated with having a positive outlook both at school and at home (Schmidt, Dirk, & Schmiedek, 2019). And in another study, in both the United States and China, parents' peer restriction predicted a decrease in children's adjustment over time (Xiong & others, 2020).

Do these findings indicate that children's peer relations always are wedded to parent-child relationships? Although parent-child relationships influence children's subsequent peer relations, children also learn other modes of relating through their relationships with peers. For example, rough-and-tumble play occurs mainly with other children, not in parent-child interaction. In times of stress, children more often turn to parents than to peers for support. Parent-child relationships teach children how to relate to authority figures. With their peers, children are likely to interact on a much more equal basis and to learn a mode of relating based on mutual influence.

Peer Contexts Peer interaction is influenced by contexts that can include the type of peer the individual interacts with–such as an acquaintance, a crowd, a clique, a friend, or a romantic partner—and the situation or location where they interact—such as a school, neighborhood, community center, dance, religious setting, sporting event, and so on, as well as the culture in which the individual lives (Shi & others, 2020). As they interact with peers in these various contexts, individuals are likely to encounter different messages and different opportunities to engage in adaptive or maladaptive behavior that can influence their development (Prinstein & Giletta, 2020).

Individual Difference Factors Individual differences among peers also are important considerations in understanding peer relations (Strickhauser & Sutin, 2020). Among the wide range of individual differences that can affect peer relations are personality traits such as how shy or outgoing an individual is. For example, a very shy individual is more likely than a gregarious individual to be neglected by peers and to feel anxious about introducing himself or herself to new peers. In a longitudinal study, shyness in childhood predicted lower emotional stability and lower extraversion in adolescence, with these links mainly due to negative peer experiences (Baardstu & others, 2020).

What are some examples of how social contexts and individual differences influence adolescents' peer relations?

What are some developmental changes in peer relations during childhood?
Hero Images/Getty Images

Developmental Changes in Childhood Around the age of 3, children already prefer to spend time with same-sex rather than opposite-sex playmates, and this preference increases in early childhood. During these same years, the frequency of peer interaction, both positive and negative, picks up considerably (Hartup, 1983). Although aggressive interaction and rough-and-tumble play increase during this period of development, there is a decreasing proportion of aggressive exchanges compared with friendly exchanges. Many preschool children spend considerable time in peer interaction just playing, conversing with peers, trying out roles, and negotiating rules. In early childhood, children distinguish between friends and nonfriends. For most young children, a friend is someone to play with. Young preschool children are more likely than older children to have friends of different gender and ethnicity (Howes, 2009).

As children enter the elementary school years, reciprocity becomes especially important in peer interchanges. Children play games together, interact in groups, and cultivate friendships. Until about 12 years of age, their preference for same-sex groups increases. The amount of time children spend in peer interaction also rises during middle and late childhood and adolescence. Researchers estimate that the percentage of time spent in social interaction with peers increases from approximately 10 percent at 2 years of age to more than 30 percent in middle and late childhood (Rubin, Bukowski, & Bowker, 2015). Other changes in peer relations as children move through middle and late childhood involve peer group expansion and peer interaction that is less closely supervised by adults (Rubin, Bukowski, & Bowker, 2015).

developmental **connection**

Social Cognition

Social cognition refers to the processes involved in understanding the world around us, especially how we think and reason about others. Connect to "The Self, Identity, and Personality."

Social Cognition A boy accidentally trips and knocks another boy's soft drink out of his hand. That boy misinterprets the encounter as hostile, which leads him to retaliate aggressively against the boy who tripped. Through repeated encounters of this kind, the aggressive boy's classmates come to perceive him as habitually acting in inappropriate ways.

This example demonstrates the importance of *social cognition*—thoughts about social matters, such as the aggressive boy's interpretation of an encounter as hostile and his classmates' perception of his behavior as inappropriate (Andrews, Ahmed, & Blakemore, 2021; Deschrijver & Palmer, 2020). Children's social cognition about their peers becomes increasingly important for understanding peer relationships in middle and late childhood. Of special interest are the ways in which children process information about peer relations and their social knowledge (Dodge, 2011a, b).

Kenneth Dodge (1983) argues that children go through six steps in processing information about their social world. They selectively attend to social cues, attribute intent, generate goals, access behavioral scripts from memory, make decisions, and enact behavior. Dodge has found that aggressive boys are more likely to perceive another child's actions as hostile when the child's intention is ambiguous. And, when aggressive boys search for cues to determine a peer's intention, they respond more rapidly, less efficiently, and less reflectively than do nonaggressive boys. These are among the social cognitive factors believed to be involved in children's and adolescents' conflicts.

What are some aspects of social cognition that are involved in getting along with peers?
Odilon Dimier/PhotoAlto/Getty Images

Social knowledge also is involved in children's ability to get along with peers (Fiske, 2018). They need to know what goals to pursue in poorly defined or ambiguous situations, how to initiate and maintain a social bond, and what scripts to follow to get other children to be their friends. For example, as part of the script for getting friends, it helps to know that making positive comments to the peer will make the peer like the child more.

Regulation of Emotion and Peer Relations Emotions play a strong role in determining whether a child's peer relationships are successful (Dollar & Calkins, 2020). Moody and emotionally

negative children are often rejected by their peers, whereas emotionally positive children are often popular (Beeson, Brittain, & Vaillancourt, 2020). The ability to engage in self-regulation and modulate one's emotions is an important skill that benefits children in their relationships with peers (Schunk, 2020). Further, adolescents are especially reliant on peers for emotional support, which was made difficult by the social isolation resulting from quarantines during the COVID-19 pandemic (Magson & others, 2021).

PEER STATUSES

Which children are likely to be popular with their peers, and which ones tend to be disliked? Developmentalists address these and similar questions by examining sociometric status, a term that describes the extent to which children are liked or disliked by their peer group (Ettekal & Ladd, 2020). Sociometric status is typically assessed by asking children to rate how much they like or dislike each of their classmates (Romera & others, 2021; Wang & Hawk, 2020). Or it may be assessed by asking children to nominate the children they like the most and those they like the least.

Developmentalists have distinguished five peer statuses (Wentzel & Asher, 1995):

- **Popular children** are frequently nominated as a best friend and are rarely disliked by their peers.
- **Average children** receive an average number of both positive and negative nominations from their peers.
- **Neglected children** are infrequently nominated as a best friend but are not disliked by their peers.
- **Rejected children** are infrequently nominated as someone's best friend and are actively disliked by their peers.
- **Controversial children** are frequently nominated both as someone's best friend and as being disliked.

What are some statuses that children have with their peers?
BananaStock/Getty Images

Popular children have a number of social skills that contribute to their being well liked (Ferguson & Ryan, 2019). Researchers have found that popular children give out reinforcements, listen carefully, maintain open lines of communication with peers, are happy, control their negative emotions, show enthusiasm and concern for others, and are self-confident without being conceited (Rubin, Bukowski, & Bowker, 2015). In one study, adolescents' popularity with their peers was associated with their dating popularity (Houser, Mayeux, & Cross, 2014). And in a recent study, being a fun person to be around was found to be an important component of peer popularity (Laursen & others, 2020).

Neglected children engage in low rates of peer interaction and are often described as shy by peers. The goal of many training programs for neglected children is to help them learn how to attract attention from their peers in positive ways and to hold that attention by asking questions, by listening in a warm and friendly way, and by saying things about themselves that relate to the peers' interests. They also are taught to enter groups more effectively.

Rejected children often have more serious adjustment problems than those who are neglected. The combination of being rejected by peers and being aggressive especially forecasts problems (Beeson, Brittain, & Vaillancourt, 2020). Peer rejection is consistently linked to the development and maintenance of conduct problems and antisocial behavior (Kornienko, Ha, & Dishion, 2020).

John Coie (2004, pp. 252–253) gave three reasons why aggressive, peer-rejected boys have problems in social relationships:

- First, the rejected, aggressive boys are more impulsive and have problems sustaining attention. As a result, they are more likely to be disruptive of ongoing activities in the classroom and in focused group play.
- Second, rejected, aggressive boys are more emotionally reactive. They are aroused to anger more easily and probably have more difficulty calming down once aroused.

Peer rejection contributes to subsequent problems of adaptation, including antisocial behavior.

–John Coie
Contemporary Developmental Psychologist, Duke University

popular children Children who are frequently nominated as a best friend and are rarely disliked by their peers.

average children Children who receive an average number of both positive and negative nominations from their peers.

neglected children Children who are infrequently nominated as a best friend but are not disliked by their peers.

rejected children Children who are infrequently nominated as a best friend and are actively disliked by their peers.

controversial children Children who are frequently nominated both as someone's best friend and as being disliked.

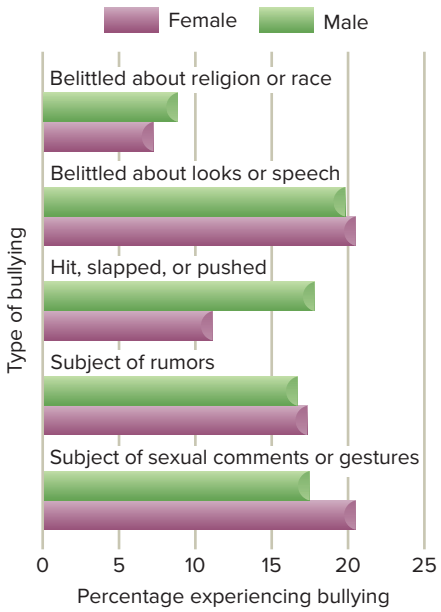

FIGURE 1

BULLYING BEHAVIORS AMONG U.S. YOUTH. This graph shows the types of bullying most often experienced by U.S. youth. The percentages reflect the extent to which bullied students said that they had experienced a particular type of bullying. In terms of gender, note that when they were bullied, boys were more likely to be hit, slapped, or pushed than girls were.

Who is likely to be bullied? What are some outcomes of bullying?
Don Hammond/Design Pics Inc./Alamy Stock Photo

Because of this, they are more prone to become angry at peers and to attack them verbally and physically.

- Third, rejected children have fewer social skills for making friends and maintaining positive relationships with peers.

Not all rejected children are aggressive (Rubin, Bukowski, & Bowker, 2015). Although aggression and its related characteristics of impulsiveness and disruptiveness underlie rejection about half the time, approximately 10 to 20 percent of rejected children are shy. Also, in a recent study, perceived peer rejection was preceded by either aggression or depression in adolescence (Beeson, Brittain, & Vaillancourt, 2020).

How can rejected children be trained to interact more effectively with their peers? Rejected children may be taught to more accurately assess whether the intentions of their peers are negative (Fontaine & others, 2010). They may be asked to engage in role playing or to discuss hypothetical situations involving negative encounters with peers, such as a peer cutting into a line ahead of them. In some programs, children are shown videotapes of appropriate peer interaction and asked to draw lessons from what they have seen (Ladd, Buhs, & Troop, 2004).

BULLYING

Significant numbers of students are victimized by bullies (Fujikawa & others, 2021; Thornberg & others, 2020). In a national survey of more than 15,000 students in grades 6 through 10, nearly one of every three students said that they had experienced occasional or frequent involvement as a victim or perpetrator in bullying (Nansel & others, 2001). In this study, bullying was defined as verbal or physical behavior intended to disturb someone less powerful (see Figure 1). Boys are more likely to be bullies than girls, but gender differences regarding victims of bullying are less clear (Salmivalli & Peets, 2018). And in a recent analysis of bullying from 1998 to 2017 in the United States, a significant increase in cyberbullying occurred (Kennedy, 2020). Also in this analysis, an increase in face-to-face bullying occurred for females.

Who is likely to be bullied? In the study just described, boys and younger middle school students were most likely to be affected (Nansel & others, 2001). Children who said they were bullied reported more loneliness and difficulty in making friends, while those who did the bullying were more likely to have low grades and to smoke and drink alcohol. Boys are more likely to be bullies than girls, but gender differences regarding victims of bullies are less clear (Salmivalli, 2020). Also, in a recent study of more than 30,000 U.S. high school students, 20 percent had experienced school bullying and 15 percent had experienced cyberbullying (Webb & others, 2021). Further, in this study, sexual minority youth were more likely to report both types of bullying victimization than their heterosexual peers, while African American and Latinx adolescents were less likely to report both types of victimization. And non-Latinx White gay/lesbian or bisexual youth reported more bullying victimization than non-Latinx White heterosexual youth.

Researchers have found that anxious, socially withdrawn, and aggressive children are often the victims of bullying (Chu & others, 2019). Anxious and socially withdrawn children may be victimized because they are nonthreatening and unlikely to retaliate if bullied, whereas aggressive children may be the targets of bullying because their behavior is irritating to bullies (Rubin & others, 2018). The social context of the peer group also plays an important role in bullying (Bjarehed & others, 2020). Recent research indicates that 70 to 80 percent of victims and their bullies are in the same school classroom (Salmivalli, 2020). Classmates are often aware of bullying incidents and likely to witness bullying. In many cases, bullies torment victims to gain higher status in the peer group, and bullies need others to witness their power displays. Many bullies are not rejected by the peer group. See the *Connecting with Research* interlude to learn about the long-term effects of bullying on children with autism spectrum disorder.

What are the outcomes of bullying? Researchers have found that children who are bullied are more likely to experience depression, engage in suicidal ideation, attempt suicide, have low self-esteem, engage in antisocial behavior, and have weight problems than their counterparts who have not been the victims of bullying (Waseem & Nickerson, 2021). One study indicated that peer victimization during the elementary school years was a leading predictor of internalizing problems (depression, for example) in adolescence (Schwartz & others, 2015). A recent Chinese study of adults age 60 years and older found that those who had been the victims of bullying in childhood had more severe depressive symptoms than their counterparts who had

connecting with research

What Are the Long-Term Effects of Bullying on Children with Autism?

Geovanna Rodriguez

Key Points:

- children with autism spectrum disorder
- approximately 40 percent are bullied
- bullying linked to mental health problems

Dr. Geovanna Rodriguez's (2021) research focuses on children and adolescents with autism spectrum disorder. In one investigation, she studied the effects of bullying on 5- to 12-year-old children diagnosed with autism (Rodriguez, Drastal, & Hartley, 2021). At two data collection points that were 12 months apart, mothers were asked to rate their children's autism symptoms on a 65-item questionnaire. Mothers were also queried about whether their child had been bullied physically, verbally, socially, and/or by cyber means over the past 4 weeks. At the same data collection times as the mothers, teachers were asked to rate the children's internalizing and externalizing mental health problems. Internalizing problems are internally focused, such as anxiety, sadness, depression, or social withdrawal. Examples of externalizing problems are aggression, conduct problems, and attention problems.

The results showed that 39 percent of the children with autism had been bullied in the month prior to the first data collection, and 41 percent had been bullied during the month prior to the second data collection. Sixty-six children who had experienced bullying at the first data collection also experienced bullying at the second data collection, suggesting that they experienced chronic bullying. Generally, children with more severe autism symptoms and higher internalizing and externalizing mental health symptoms at the first data collection experienced a higher frequency of bullying at the second data collection. Analysis revealed that older children with autism also experienced a higher frequency of bullying. And there were no differences in bullying based on gender or level of intellectual disability.

In addition, bullying victimization and externalizing mental health problems, such as aggression and hyperactivity, were present at both data collections and did not change over the 12-month period. In contrast, bullying changed the incidence of internalizing mental health problems: Children who were victims of bullying at the first data collection and at that time had showed no internalizing mental health problems had developed these problems, such as anxiety and withdrawn behavior, by the time of the second data collection. Further, for more than one-third of the sample, bullying victimization was chronic and characterized by externalizing mental health problems.

Among the most important contributions of this investigation was the finding that bullying victimization of younger children without internalizing mental health problems may contribute, along with age, to the development of internalizing problems across a 12-month period. While the prevention of bullying is of primary importance, understanding the time-related sequencing of symptoms can allow parents, teachers, and therapists to better understand the effects of bullying on the psychological well-being of children with autism.

How can researchers ensure that results that shed light on the effects of bullying children with autism spectrum disorder are properly applied in school settings?

not experienced bullying victimization as children (Hu, 2021). Also, in a recent study of 12- to 15-year-olds in 48 countries worldwide, being a victim of bullying was a risk factor for suicidal behavior in 47 of the 48 countries (Koyanagi & others, 2019). In addition, a longitudinal study revealed that after being bullied, bullying victims' self-esteem decreased, and this lower self-esteem was linked to being further bullied (Choi & Park, 2021). And in a recent study of more than 150,000 12- to 15-year-olds in 54 low- and middle-income countries, victims of bullying were more likely to be characterized by the following obesity-related factors: anxiety-induced sleep problems, no physical activity, sedentary behavior, and fast food consumption (Smith & others, 2021).

Meta-analyses have concluded that engaging in bullying during middle school is linked to an increased likelihood of antisocial and criminal behavior later in adolescence and adulthood (Kim & others, 2011). Also, a longitudinal study found that children who were bullied at 6 years of age were more likely to have excessive weight gain when they were 12 to 13 years of age (Sutin & others, 2016). Further, a recent large-scale Norwegian study concluded that bullies, victims, and bully-victims all are at risk for developing sleep problems, including shorter sleep duration and a higher prevalence of insomnia, as well as a lower grade point average (Hysing & others, 2020). In addition, a research analysis concluded that bullying can have long-term negative effects, including difficulty in forming lasting relationships and problems in the workplace (Wolke & Lereya, 2015). In addition, another recent study revealed that being a victim of bullying in childhood was linked to increased use of mental health services by the victims five decades later (Evans-Lacko & others, 2017).

An increasing concern is peer bullying and harassment on the Internet (called *cyberbullying*) (Armitage, 2021; Barlett & others, 2021). One study involving third- to sixth-graders revealed that engaging in cyber aggression was related to loneliness, lower self-esteem, fewer mutual friendships, and lower peer popularity (Schoffstall & Cohen, 2011). Also, a recent study of university students indicated that being a cybervictim increased the risk of suicidal thinking as well as high levels of anxiety, stress, and depression (Martinez-Monteagudo & others, 2020). Information about preventing cyberbullying can be found at www.stopcyberbullying.org/.

Extensive interest is being directed to finding ways to prevent and treat bullying and victimization (Swearer & others, 2021). School-based interventions vary greatly, ranging from involving the whole school in an anti-bullying campaign to providing individualized social skills training (Strohmeier & Noam, 2012). One of the most promising bullying intervention programs has been created by Scandinavian researcher Dan Olweus (2003, 2013). This program focuses on 6- to 15-year-olds, with the goal of decreasing opportunities and rewards for bullying. School staff are instructed in ways to improve peer relations and make schools safer. When properly implemented, the program reduces bullying by 30 to 70 percent (Olweus, 2003). A research review concluded that interventions focused on the whole school, such as Olweus', are more effective than interventions involving classroom curricula or social skills training (Cantone & others, 2015).

GENDER AND PEER RELATIONS

We know that boys are far more likely to be involved in bullying than girls are. Indeed, there is increasing evidence that gender plays an important role in peer relations, as we saw in the chapter on "Gender and Sexuality" (Felton & others, 2019; Rose & Smith, 2018). Gender influences the composition of children's groups, their size, and the interaction within groups (Maccoby, 2002):

- *Gender composition*. Around the age of 3, children already prefer to spend time with same-sex playmates. From 4 to 12 years of age, this preference for playing in same-sex groups increases (see Figure 2).
- *Group size*. From about 5 years of age onward, boys tend to associate in larger clusters than girls do. Girls are more likely than boys to play in groups of two or three.
- *Interaction in same-sex groups*. Boys are more likely to participate in organized group games than girls are. They also are more likely to engage in rough-and-tumble play, competition, conflict, ego displays, risk taking, and dominance seeking. By contrast, girls are more likely to engage in "collaborative discourse."

ADOLESCENT PEER RELATIONS

Peers play powerful roles in the lives of adolescents (Prinstein & Giletta, 2020). And just as there are gender differences in peer relations in childhood, adolescent peer relations are influenced by gender (Rose and Smith, 2018). A meta-analysis concluded that adolescent girls show stronger peer attachment, especially related to trust and communication, than do adolescent boys (Gorrese & Ruggieri, 2012).

Children usually socialize in informal collections of friends or neighborhood acquaintances, while adolescents are often members of formal and heterogeneous groups. Such groups often include adolescents who may not be friends or neighborhood acquaintances. Adolescent groups are also more likely than childhood groups to include both boys and girls.

Peer Contexts Nowhere have the changing influences on peer relations been more evident in recent years than the increased connections adolescents make with peers and friends through networked technologies (Massing-Schaffer & others, 2020). Compared with earlier decades when the vast majority of adolescent contacts with peers and friends were made in person, today adolescents also spend considerable time using social media to connect with peers and friends (Prinstein, Nesi, & Telzer, 2020). Text messaging has become the main way adolescents connect with friends, surpassing even face-to-face contact (Lenhart, 2015a, b).

A recent analysis described five ways in which social media transform adolescent peer relationships (Nesi, Choukas-Bradley, & Prinstein, 2018):

1. *Changing the frequency or immediacy of experiences* (potential for immediate, frequent social support, reassurance, negative feedback, and co-rumination)

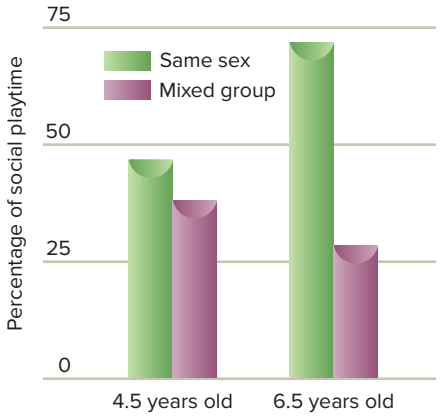

FIGURE **2**

DEVELOPMENTAL CHANGES IN PERCENTAGE OF TIME SPENT IN SAME-SEX AND MIXED-GROUP SETTINGS. Observations of children show that they are more likely to play in same-sex than mixed-sex groups. This tendency increases between 4 and 6 years of age.

2. *Amplifying experiences and demands* (heightened feedback seeking and expectations for relationship maintenance and access)
3. *Altering the qualitative aspects of interactions* (less rich social support, increased comfort in interactions)
4. *Facilitating new opportunities for compensatory behaviors* (possible exclusive online relationships and communication with geographically distant friends)
5. *Creating completely novel behaviors* (new opportunities to publicize "top friends" and relationships

Later in this chapter we will further discuss adolescents' use of social media.

How might social media influence peer relationships?
Peathegee Inc/Blend Images LLC

Peer Pressure Young adolescents conform more closely to peer standards than children do (Prinstein & Giletta, 2020). Around the eighth and ninth grades, conformity to peers—especially to their antisocial standards—peaks (Brechwald & Prinstein, 2011). At this point, adolescents are most likely to go along with a peer to cheat on a test, draw graffiti on a wall, or steal cosmetics from a store counter. Adolescents are more likely to conform to their peers when they are uncertain about their social identity and when they are in the presence of someone they perceive to have higher status than they do (Prinstein & Giletta, 2016). Also, one study found that boys were more likely to be influenced by peer pressure involving sexual behavior than were girls (Widman & others, 2016). And a recent study of eighth-graders revealed that peer pressure was associated with substance use (Jelsma & Varner, 2020).

Cliques and Crowds Cliques and crowds assume more important roles in the lives of adolescents than in the lives of children (Zarbatany & others, 2019). **Cliques** are small groups that range from 2 to about 12 individuals and average about 5 or 6 individuals. The clique members are usually of the same sex and about the same age.

Cliques can form because adolescents engage in similar activities, such as being in a club or on a sports team. Some cliques also form because of friendship. Several adolescents may form a clique because they have spent time with each other, share mutual interests, and enjoy each other's company. Not necessarily friends, they often develop friendships if they stay in the clique. What do adolescents do in cliques? They share ideas and hang out together. Often they develop an in-group identity in which they believe that their clique is better than other cliques.

What characterizes peer pressure in adolescence? What characterizes adolescent cliques? How are they different from crowds?
Christin Rose/Image Source/Getty Images

Crowds are larger than cliques and less personal. Adolescents are usually members of a crowd based on reputation, and they may or may not spend much time together. Many crowds are defined by the activities adolescents engage in (such as "jocks" who are good at sports, "brains" who excel in academics, or "druggies" who take drugs). In a recent study of adolescents, risky behavior was associated with two crowds—the Hip Hop crowd was especially linked with substance use and violence and the alternative crowd was associated with substance use, depression, suicide, bullying, physical inactivity, and obesity (Jordan & others, 2019). Also in this study, the mainstream and popular crowds were characterized by a lower level of risk taking for most behaviors.

So far, we have discussed many aspects of friendship and peer relations in adolescence. A final point about these very important socioemotional interactions of adolescents is how the abrupt appearance of the COVID-19 pandemic in 2020 quickly changed the ways friendship and peer relations take place (Andrews, Foulkes, & Blakemore, 2020). One of the most widely emphasized changes is the impact of *social distancing*, which involves maintaining a distance of 6 feet or more from others to prevent getting the virus or giving the virus to them. For some individuals, social distancing may increase feelings of social isolation and decrease the all-important sense of connection with peers and friends. One benefit of the dramatic increase in social media use is that it lets adolescents at least stay connected with friends and peers online. Although adolescents are likely to press parents to let them congregate in person with peers and friends, given the potential damaging consequences of such viruses it is important for parents to not give into such demands when infections are rampant, especially when the interactions involve groups, and to let adolescents know that eventually they will be able to go back to engaging in normal in-person friendship and peer interactions.

cliques Small groups that range from 2 to 12 individuals and average about 5 or 6 individuals. Clique members usually are of the same age and same sex and often engage in similar activities, such as belonging to a club or participating in a sport.

crowds A crowd is a larger group than a clique. Adolescents usually are members of a crowd based on reputation and may not spend much time together. Many crowds are defined by the activities in which adolescents engage.

Connect

- Most developmentalists agree that peers play an important role in the development of moral reasoning. Of the five peer status groups you learned about in this section of the chapter, in which one(s) do you think children would have the least opportunity to fully develop their moral reasoning capacities, and why?

Reflect *Your Own Personal Journey of Life*

- Think back to your childhood and adolescent years. Which peer status would you use to describe yourself? How influential do you think your peer status was on your development?

2 Friendship

LG2 Explain the role of friendship through the life span.

Functions of Friendship | Friendship During Childhood | Friendship During Adolescence and Emerging Adulthood | Friendship During Adulthood

A man's growth is seen in the successive choirs of his friends.

—Ralph Waldo Emerson
American Author and Poet, 19th Century

The world of peers is one of varying acquaintances; each day we interact with some people we barely know and with others we know well. It is to the latter type—friends—that we now turn.

FUNCTIONS OF FRIENDSHIP

Why are friendships important? They serve the following functions (Gottman & Parker, 1987):

- *Companionship*. Friendship provides a familiar partner and playmate, someone who is willing to spend time with us and join in collaborative activities.
- *Stimulation*. Friendship provides interesting information, excitement, and amusement.
- *Ego support*. Friendship provides the expectation of support, encouragement, and feedback, which helps us maintain an impression of ourselves as competent, attractive, and worthwhile individuals.
- *Social comparison*. Friendship provides information about where we stand vis-à-vis others and how we are doing.
- *Affection and intimacy*. Friendship provides a warm, close, trusting relationship with another individual. **Intimacy in friendships** is characterized by self-disclosure and the sharing of private thoughts. Research reveals that intimate friendships may not appear until early adolescence (Berndt & Perry, 1990).

intimacy in friendship Self-disclosure and the sharing of private thoughts.

FRIENDSHIP DURING CHILDHOOD

Children's friendships are typically characterized by similarity (referred to as homophily, the tendency to associate with similar others) (David-Barrett, 2020). Similarity is a central aspect of friendship that may or may not be beneficial (Prinstein & Giletta, 2016). Throughout childhood,

friends are more similar than dissimilar in terms of age, sex, ethnicity, and many other factors. Friends often have similar attitudes toward school, similar educational aspirations, and closely aligned achievement orientations.

Although having friends can be a developmental advantage, all friendships are not alike (Graham & Kogachi, 2021). People differ in the company they keep—that is, who their friends are. Developmental advantages occur when children have friends who are socially skilled, supportive, and oriented toward academic achievement (Ryan & Shin, 2018). However, it is not developmentally advantageous to have coercive, conflict-ridden, and poor-quality friendships (Clayton & others, 2020). One study found that students who engaged in aggressive-disruptive behavior in the classroom were more likely to have aggressive friends (Powers & Bierman, 2013). To read about strategies for helping children develop friendships, see the *Connecting Development to Life* interlude.

What characterizes children's friendships?

FRIENDSHIP DURING ADOLESCENCE AND EMERGING ADULTHOOD

How are adolescent friendships different from childhood friendships? What characterizes friendship in emerging adulthood?

Adolescence For most adolescents, being popular with their peers is a strong motivator. The focus of their peer relations is on being liked by classmates and being included in games and lunchroom conversations. Beginning in early adolescence, however, teenagers typically prefer to have a smaller number of friendships that are more intense and intimate than those of young children.

Harry Stack Sullivan (1953) has been the most influential theorist in the study of adolescent friendships. Sullivan argued that friends are important in shaping the development of children and adolescents. Everyone, said Sullivan, has basic social needs, such as the need for secure attachment, playful companionship, social acceptance, intimacy, and sexual relations. Whether or not these needs are fulfilled largely determines our emotional well-being. For example, if the need for playful companionship goes unmet, then we become bored and depressed; if the need for social acceptance is not met, we suffer a diminished sense of self-worth.

During adolescence, said Sullivan, friends become increasingly important in meeting social needs. In particular, Sullivan argued that the need for intimacy intensifies during early adolescence, motivating teenagers to develop close friendships. If adolescents fail to forge such close friendships, they often feel lonely and inadequate.

connecting development to life

Effective and Ineffective Strategies for Making Friends

Here are some strategies that adults can recommend to children and adolescents for making friends (Wentzel, 1997):

- ***Initiate interaction***. **Learn about a friend: Ask for his or her name, age, favorite activities. Use these prosocial overtures: Introduce yourself, start a conversation, and invite him or her to do things.**
- ***Be nice***. **Show kindness, be considerate, and compliment the other person.**
- ***Engage in prosocial behavior***. **Be honest and trustworthy: Tell the truth, keep promises. Be generous, share, and be cooperative.**
- ***Show respect for yourself and others***. **Have good manners, be polite and courteous, and listen to what others have to say. Have a positive attitude and personality.**
- ***Provide social support***. **Show you care.**

And here are some ineffective strategies for making friends that adults can advise children and adolescents to avoid (Wentzel, 1997):

- ***Be psychologically aggressive***. **Show disrespect and have bad manners. Use others, be uncooperative, don't share, ignore others, gossip, and spread rumors.**
- ***Present yourself negatively***. **Be self-centered, snobby, conceited, and jealous; show off, care only about yourself. Be mean, have a bad attitude, be angry, throw temper tantrums, and start trouble.**
- ***Behave antisocially***. **Be physically aggressive, yell at others, pick on them, make fun of them, be dishonest, tell secrets, and break promises.**

These suggestions were developed for adults to use in guiding children. Do you think there is any period of the life span in which they would not be appropriate? Are some more effective in some periods of the life span than in others? If so, which ones and why?

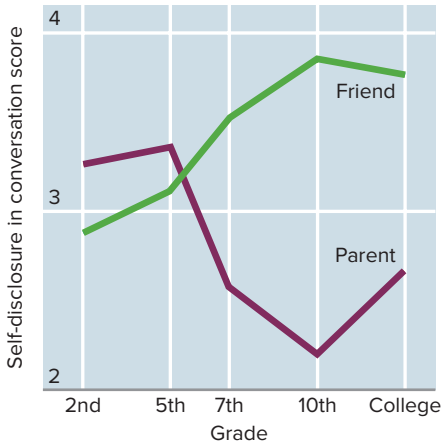

FIGURE **3**

DEVELOPMENTAL CHANGES IN SELF-DISCLOSING CONVERSATIONS. Self-disclosing conversations with friends increase dramatically in adolescence while self-disclosure with parents declines in an equally dramatic fashion. However, self-disclosing conversations with parents begin to pick up somewhat during the college years. In this study, self-disclosure was measured using a five-point rating scale completed by the children and youth, with a higher score representing greater self-disclosure. The data shown represent the means for each age group.

Many of Sullivan's ideas have withstood the test of time. For example, adolescents report disclosing intimate and personal information to their friends more often than younger children do (Buhrmester, 1998) (see Figure 3). Adolescents also say they depend more on friends than on parents to satisfy their needs for companionship, reassurance of worth, and intimacy. The ups and downs of experiences with friends shape adolescents' well-being (Laursen, 2018).

Are the friendships of adolescent girls more intimate than the friendships of adolescent boys? Girls' friendships in adolescence are more likely to focus on intimacy; boys' friendships tend to emphasize power and excitement (Rose & Smith, 2018). Boys may discourage one another from openly disclosing their problems because self-disclosure is not considered masculine (Maccoby, 1998).

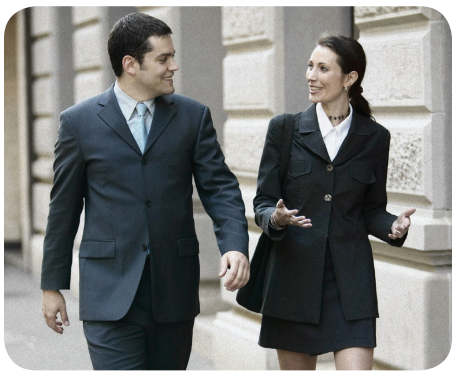
A study of third- through ninth-graders by Amanda Rose and her colleagues (Rose, Carlson, & Waller, 2007), though, revealed that one aspect of girls' social support in friendship may have costs as well as benefits. In the study, girls' co-rumination (as reflected in excessively discussing problems) predicted not only an increase in positive friendship quality but also an increase in further co-rumination as well as an increase in symptoms of depression and anxiety. One implication of the research is that some girls who are vulnerable to developing internalized problems may go undetected because they have supportive friendships. Other recent research confirms the influence of co-rumination in friendship. For example, in a recent study, friendship intensity was an amplifier of an adolescent's preexisting tendencies toward depression or aggression (Costello & others, 2020). These findings indicate that co-rumination for depression and aggression are both likely to increase in the context of higher-intensity friendships.

The studies just described indicate that the characteristics of an adolescent's friends can influence whether the friends have a positive or negative influence on the adolescent (Felton & others, 2019). Positive relationships with friends in adolescence are associated with a host of positive outcomes, including lower rates of delinquency, substance abuse, risky sexual behavior, and bullying victimization, and higher levels of academic achievement and physical exercise (Ryan & Shin, 2018). In a recent study of young adolescents, for non-Latinx White and Asian American adolescents, higher academic achievement was linked to having same-ethnic friends, while for African American and Latinx adolescents, higher academic achievement was associated with having more cross-ethnic friendships (Chen, Saafir, & Graham, 2020).

Not having a close relationship with a best friend, having less contact with friends, having friends who are depressed, and experiencing peer rejection all increase depressive tendencies in adolescents (Bukowski, Laursen, & Rubin, 2018). Researchers have found that interacting with delinquent peers and friends greatly increases the risk of becoming delinquent (Walters, 2020). One study found that adolescents adapted their smoking and drinking behavior to match that of their best friends (Wang & others, 2016). Another recent study of adolescent girls revealed that friends' dieting predicted whether an adolescent girl would engage in dieting or extreme dieting (Balantekin, Birch, & Savage, 2018). In addition, a recent study indicated that peers' influence on adolescents' food choices is often negative and characterized by an increase in consumption of energy-dense and low-nutrition foods (Rageliene & Granhoj, 2020). Further, a recent study of Saudi Arabian adolescents indicated that they had elevated levels of suicidal thoughts and behavior when their friends disclosed depression and self-harm (Copeland & others, 2020). However, a recent meta-analytic review concluded that friendship experiences may be more closely related to loneliness than to depressive symptoms (Schwartz-Mette & others, 2020).

Although most adolescents develop friendships with individuals who are close to their own age, some adolescents become best friends with younger or older individuals. Do older friends encourage adolescents to engage in delinquent behavior or early sexual behavior? Adolescents who interact with older youth do engage in these behaviors more frequently, but it is not known whether the older youth guide younger adolescents toward deviant behavior or whether the younger adolescents were already prone to deviant behavior before they developed friendships with older youth (Billy, Rodgers, & Udry, 1984). A study also revealed that over time from the sixth through tenth grades girls were more likely to have older male friends, which places some girls on a developmental trajectory for engaging in problem behavior (Poulin & Pedersen, 2007).

Emerging Adulthood Many aspects of friendship are the same in emerging adulthood as they were in adolescence. One difference was found, however, in a longitudinal study (Collins & van Dulmen, 2006). Close relationships—between friends, family members, and romantic partners—were more integrated and similar in emerging adulthood than they were in



How is adult friendship different among female friends, male friends, and cross-gender friends?
(*Left to right*): Stockbyte/Stockdisc/Getty Images; Loreanto/Shutterstock; Ingram Publishing/age fotostock

adolescence. Also in this study, the number of friendships declined from the end of adolescence through emerging adulthood.

Another research study indicated that best friendships often decline in satisfaction and commitment in the first year of college (Oswald & Clark, 2003). In this study, maintaining communication with high school friends and keeping the same best friends across the transition to college lessened the decline.

FRIENDSHIP DURING ADULTHOOD

As in childhood and adolescence, adult friends tend to be similar in a number of ways. Among the similarities in friendship during the adult years are occupational status, ethnicity, age, marital status, income, education, gender, and religion (Rawlins, 2009).

developmental **connection**
Gender
Deborah Tannen emphasizes gender differences in report talk and rapport talk. Connect to "Gender and Sexuality."

Gender Differences As in the childhood and adolescent years, there are gender differences in adult friendships. Women have more close friends than men do, and their friendships are more intimate (Wood, 2011, 2012). When adult women friends get together, they often talk, whereas adult men friends are more likely to engage in activities, especially outdoors. Thus, the adult man's pattern of friendship often involves keeping a distance while sharing useful information. When women talk with their friends, they expect to be able to express their feelings, reveal their weaknesses, and discuss their problems. They anticipate that their friends will listen at length and be sympathetic. In contrast, men are less likely to talk about their weaknesses with their friends, and they want practical solutions to their problems rather than sympathy (Tannen, 1990). Also, friendships among adult men are more competitive than those of women (Sharkey, 1993). For example, male friends disagree with each other more. Keep in mind, however, that these differences in same-gender adult friendships tend to be small (Sabini, 1995).

What about friendship between women and men? Cross-gender friendships are more common among adults than among elementary school children, but not as common as same-gender friendships (Wood, 2011, 2012). Cross-gender friendships can provide both opportunities and problems (Trinh & Choukas-Bradley, 2018). The opportunities involve learning more about common feelings and interests and shared characteristics, as well as acquiring knowledge and understanding of beliefs and activities that historically have been typical of the other gender.

Problems can arise in cross-gender friendships because of different expectations. For example, a woman might expect sympathy from a male friend but might receive a directive solution rather than a shoulder to cry on (Tannen, 1990). Another problem that can plague adult cross-gender friendship is unclear sexual boundaries, which can produce tension and confusion (Swain, 1992).

Friendship in Late Adulthood In early adulthood, friendship networks expand as new social connections are made away from home. In late adulthood, new friendships are less likely to be forged, although some adults do seek out new friendships, especially following the death of a spouse (Blieszner & Ogletree, 2017, 2018).

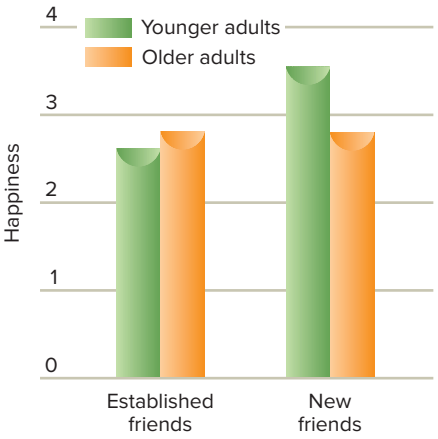
Aging expert Laura Carstensen and her colleagues (1998, 2009; Sims, Hogan, & Carstensen, 2015) concluded that people choose close friends over new friends as they grow older. And as long as they have several close people in their network, they seem content, says Carstensen.

What are some characteristics of older adults' friendships?
kali9/Getty Images

FIGURE 4

HAPPINESS OF YOUNGER ADULTS AND OLDER ADULTS WITH NEW AND ESTABLISHED FRIENDS.

Note: The happiness scale ranged from 0 to 6, with participants rating how intensely they experienced happiness (0 = not at all, 6 = extremely intense). Older adults' mean age was 71; younger adults' mean age was 23.



Supporting Carstensen's view, researchers found that in comparison with younger adults, older adults said they tended to experience less intense positive emotions with new friends and equal levels of positive emotions with established friends (Charles & Piazza, 2007) (see Figure 4). Carstensen also states that it is important to remember that older adults are happier and less lonely than young adults. And in a recent study, compared with younger adults, older adults reported fewer problems with friends, fewer negative friendship qualities, less frequent contact with friends, and more positive friendship qualities with a specific friend (Schlosnagle & Strough, 2017).

In other research, adults 75 years of age and older who maintained close ties with friends were less likely to die across a seven-year age span (Rasulo, Christensen, & Tomassini, 2005). The findings were stronger for women than for men. Further, in a recent study of older couples, having a larger friend confidant network or closer connections with friend confidants was linked to better marital quality for wives and husbands five years later (Zhaoyang & Martire, 2020). And in another recent study of older adults, interactions with friends were more pleasant and were associated with fewer discussions about stressful experiences than were interactions with partners or family members (Ng & others, 2020).

3 Play and Leisure

LG3 Describe the developmental aspects of play and leisure.

Childhood | Adolescence | Adulthood

You are troubled at seeing him spend his early years in doing nothing. What! Is it nothing to be happy? Is it nothing to skip, to play, to run about all day long? Never in his life will he be so busy as now.

—Jean-Jacques Rousseau
Swiss-born French Philosopher, 18th Century

Peers and friends often engage in play and enjoy leisure activities together. Let's explore the developmental aspects of play and leisure.

CHILDHOOD

An extensive amount of peer interaction during childhood involves play; however, social play is but one type of play (Graham, 2020). **Play** is a pleasurable activity that is engaged in for its own sake.

Play's Functions Play is an important aspect of children's development (Reaney, 2020). Theorists have focused on different aspects of play and highlighted a long list of functions.

According to Freud and Erikson, play helps the child master anxieties and reduce conflicts (Demanachick, 2015). Because tensions are relieved in play, the child can cope more effectively with life's problems. Play permits the child to work off excess physical energy and release pent-up tensions. Therapists use **play therapy** both to allow the child to release frustrations and to analyze the child's conflicts and ways of coping with them. Children may feel less threatened and be more likely to express their true feelings in the context of play (Clark, 2016).

Piaget (1962) maintained that play advances children's cognitive development. At the same time, he said that children's cognitive development constrains the way they play. Play permits children to practice their competencies and skills in a relaxed, pleasurable way (Hirsh-Pasek & Golinkoff, 2014). Piaget thought that cognitive structures need to be exercised, and play provides the perfect setting for this exercise (DeLisi, 2015). For example, children who have just learned to add or multiply may begin to play with numbers in different ways as they perfect these operations, laughing as they do so.

Vygotsky (1962) also considered play to be an excellent setting for cognitive development. He was especially interested in the symbolic and make-believe aspects of play, as when a child substitutes a stick for a horse and rides the stick as if it were a horse (Bodrova & Leong, 2015a, b). For young children, the imaginary situation is real. Parents should encourage such imaginary play, because it advances the child's cognitive development, especially creative thought. Both Piaget and Vygotsky described play as the work of the child.

Daniel Berlyne (1960) described play as exciting and pleasurable in itself because it satisfies our exploratory drive. This drive involves curiosity and a desire for information about something new or unusual. Play is a means whereby children can safely explore and seek out new information. Play encourages exploratory behavior by offering children the possibilities of novelty, complexity, uncertainty, surprise, and incongruity.

More recently, play has been described as an important context for the development of language and communication skills (Taggart, Eisen, & Lillard, 2018). Language and communication skills may be enhanced through discussions and negotiations regarding roles and rules in play as young children practice various words and phrases. These types of social interactions during play can benefit young children's literacy skills (Bredekamp, 2020). Play is a central focus of the child-centered kindergarten and is thought to be an essential aspect of early childhood education (Morrison, Woika, & Breffni, 2020).

An increasing concern is that the large number of hours children spend with electronic media, such as television and computers, takes time away from play (Hnatiuk & others, 2020). A recent study of 2- to 5-year-olds found that television/DVD/video viewing was negatively linked to young children's social skills, while outdoor play was positively associated with their social skills (Hinkley & others, 2018). Thus, an important agenda for parents is to include ample time for play in their children's lives.

Types of Play The contemporary perspective on types of play emphasizes both cognitive and social aspects of play (Richards, 2020). Among the most widely studied types of children's play today are sensorimotor and practice play, pretense/symbolic play, social play, constructive play, and games.

Sensorimotor and Practice Play **Sensorimotor play** is behavior by infants to derive pleasure from exercising their sensorimotor schemes. The development of sensorimotor play follows Piaget's description of sensorimotor thought. Infants initially engage in exploratory and playful visual and motor transactions in the second quarter of the first year of life. By the end of the third quarter, infants begin to select novel objects for exploration and play, especially responsive objects such as toys that make noise or bounce. At 12 months of age, infants enjoy making things work and exploring cause and effect.

Practice play involves repetition of behavior when new skills are being learned or when physical or mental mastery and coordination of skills are required for games or sports. Sensorimotor play, which often involves practice play, is primarily confined to infancy, whereas practice play can be engaged in throughout life. During the preschool years, children frequently engage in practice play. Although practice play declines in the elementary school years, practice play activities such as running, jumping, sliding, twirling, and throwing balls or other objects are frequently observed on playgrounds at elementary schools.

Pretense/Symbolic Play **Pretense/symbolic play** occurs when the child transforms aspects of the physical environment into symbols. Between 9 and 30 months of age, children

developmental **connection**

Education

The child-centered kindergarten emphasizes the education of the whole child and the importance of play in young children's development. Connect to "Schools, Achievement, and Work."

increase their use of objects in symbolic play. They learn to transform objects—substituting them for other objects and acting toward them as if they were those other objects (Taggart, Eisen, & Lillard, 2018). For example, a preschool child treats a table as if it were a car and says, "I'm fixing the car," as he grabs a leg of the table.

Many experts on play consider the preschool years the "golden age" of symbolic/pretense play that is dramatic or sociodramatic in nature. This type of make-believe play often appears at about 18 months of age and reaches a peak at 4 to 5 years of age, then gradually declines.

Some child psychologists conclude that pretense/symbolic play is an important aspect of young children's development and often reflects advances in their cognitive development, especially as an indication of symbolic understanding (Taggart, Eisen, & Lillard, 2018). For example, Catherine Garvey (2000) and Angeline Lillard (2015) emphasize that hidden in young children's pretend play narratives are capacities for role-taking, balancing of social roles, metacognition (thinking about thinking), testing of the reality-pretense distinction, and numerous non-egocentric capacities that reveal the remarkable cognitive skills of young children.

Social Play **Social play** is play that involves interaction with peers. Social play increases dramatically during the preschool years (Solovieva & Quintanar, 2017). Social play includes varied interchanges such as turn taking, conversations about numerous topics, social games and routines, and physical play (Sumaroka & Bornstein, 2008). Social play often involves a high degree of pleasure on the part of the participants (Sumaroka & Bornstein, 2008).

Constructive Play **Constructive play** combines sensorimotor/practice play with symbolic representation. Constructive play occurs when children engage in the self-regulated creation of a product or a solution. Constructive play increases in the preschool years as symbolic play increases and sensorimotor play decreases. In the preschool years, some practice play is replaced by constructive play. For example, instead of moving their fingers around and around in finger paint (practice play), children are more likely to draw the outline of a house or a person in the paint (constructive play). Constructive play is also a frequent form of play in the elementary school years, both within and outside the classroom.

Games **Games** are activities that are engaged in for pleasure and have rules. Often they involve competition. Preschool children may begin to participate in social games that involve simple rules of reciprocity and turn taking. However, games take on a much stronger role in the lives of elementary school children.

In sum, play ranges from an infant's simple exercise of a new sensorimotor skill to a preschool child's riding a tricycle to an older child's participation in organized games. Note that children's play can involve a combination of the play categories we have discussed. For example, social play can be sensorimotor (rough-and-tumble), symbolic, or constructive.

Trends in Play Kathy Hirsh-Pasek, Roberta Golinkoff, and Dorothy Singer (Hirsh-Pasek & others, 2009; Singer, Golinkoff, & Hirsh-Pasek, 2006) are concerned about the limited amount of time that young children engage in free play, reporting that it has declined considerably in recent

Activity	Nonindustrial, Unschooled Populations	Postindustrial, Schooled Populations		
		United States	Europe	East Asia
TV viewing	Insufficient data	1.5 to 2.5 hours	1.5 to 2.5 hours	1.5 to 2.5 hours
Talking	Insufficient data	2 to 3 hours	Insufficient data	45 to 60 minutes
Sports	Insufficient data	30 to 60 minutes	20 to 80 minutes	0 to 20 minutes
Structured voluntary activities	Insufficient data	10 to 20 minutes	10 to 20 minutes	0 to 10 minutes
Total free time	4 to 7 hours	6.5 to 8.0 hours	5.5 to 7.5 hours	4.0 to 5.5 hours

Note: The estimates in the table are averaged across a 7-day week, including weekdays and weekends. The data for nonindustrial, unschooled populations come primarily from rural peasant populations in developing countries.

FIGURE 5

AVERAGE DAILY LEISURE TIME OF ADOLESCENTS IN DIFFERENT REGIONS OF THE WORLD.

decades. They especially are worried about young children's playtime being restricted at home and school so they can spend more time on academic subjects. They also point out that many schools have eliminated recess. And it is not just the decline in free play time that bothers them. They underscore that learning in playful contexts captivates children's minds in ways that enhance their cognitive and socioemotional development. In fact, Singer, Golinkoff, and Hirsh-Pasek's (2006) first book on play was titled *Play = Learning.* Among the cognitive benefits of play they described are the development of creative, abstract thinking; imagination; attention, concentration, and persistence; problem-solving; social cognition, empathy, and perspective taking; language; and mastering new concepts. Among the socioemotional experiences and development they believe play promotes are enjoyment, relaxation, and self-expression; cooperation, sharing, and turn-taking; anxiety reduction; and self-confidence. With so many positive cognitive and socioemotional outcomes of play, clearly it is important that we find more time for play in young children's lives (Graham, 2020).

leisure The pleasant times when individuals are free to pursue activities and interests of their own choosing.

ADOLESCENCE

Leisure refers to the pleasant times when individuals are free to pursue activities and interests of their own choosing—hobbies, sports, or reading, for example. How much leisure time do U.S. adolescents have in comparison with adolescents in other countries? How do U.S. adolescents use their leisure time?

Figure 5 indicates that U.S. adolescents spend more time in leisure activities than do adolescents in other industrialized countries (Larson & Verma, 1999). About 40 to 50 percent of U.S. adolescents' waking hours (not counting summer vacation) is spent in leisure activities, compared with 25 to 35 percent in East Asia and 35 to 45 percent in Europe. Whether this additional leisure time is a liability or an asset for U.S. adolescents, of course, depends on how they use it.

The largest amounts of U.S. adolescents' free time are spent engaging in screen-based activities, hanging out, and engaging in unstructured leisure activities, often with friends. U.S. and European adolescents spend more time in voluntary structured activities—such as sports, hobbies, and organizations—than East Asian adolescents do.

According to Reed Larson and his colleagues (Larson, 2001, 2020; Larson, Walker, & McGovern, 2020; Larson & others, 2019), in terms of optimal development U.S. adolescents may have too much unstructured time because when

Sigmund Freud said that the two things adults need to do well to adapt to society's demands are to work and to love. To his list we add "to play." In our fast-paced society, it is all too easy to get caught up in the frenzied, hectic pace of our achievement-oriented work world and ignore leisure and play. *Imagine your life as a middle-aged adult. What would be the ideal mix of work and leisure? What leisure activities do you want to enjoy as a middle-aged adult?*
wundervisuals/Getty Images

they are allowed to choose what to do with their time, they typically engage in unchallenging leisure activities such as hanging out and watching TV. Although relaxation and social interaction are important aspects of adolescence, it seems unlikely that spending large numbers of hours per week in unchallenging activities fosters development. Structured voluntary activities may hold more promise for adolescent development than unstructured time, especially if adults give responsibility to adolescents, challenge them, and provide competent guidance in these activities (Griffith & others, 2020).

ADULTHOOD

As adults, not only must we learn how to work well, but we also need to learn how to relax and enjoy leisure (Fancourt & others, 2021). In an analysis of what U.S. adults regret the most, not engaging in more leisure was one of the top six regrets (Roese & Summerville, 2005).

Leisure can be an especially important aspect of middle adulthood (Piirtola & others, 2020). By middle adulthood, more money is available to many individuals, and there may be more free time and paid vacations. In short, midlife changes may produce expanded opportunities for leisure. For many individuals, middle adulthood is the first time in their lives when they have the opportunity to diversify their interests.

In one study, 12,338 men 35 to 57 years of age were assessed each year for five years regarding whether they took vacations or not (Gump & Matthews, 2000). Then the researchers examined the medical and death records over nine years for men who lived for at least a year after the last vacation survey. Compared with those who never took vacations, men who went on annual vacations were 21 percent less likely to die over the nine years and 32 percent less likely to die of coronary heart disease.

Recent research further indicates the importance of leisure in cognitive and health outcomes (Werneck & others, 2019). A Danish longitudinal study of 20- to 93-year-olds found that those who engaged in a light level of leisure-time physical activity lived 2.8 years longer, those who engaged in a moderate level of leisure-time physical activity lived 4.5 years longer, and those who engaged in high level of leisure-time physical activity lived 5.5 years longer (Schnohr & others, 2017). Also, a recent Korean study of 40- to 69-year-olds confirmed that engaging in leisure-time physical activity was linked to a lower risk of death, with those who engaged in vigorous and intense exercise benefitting the most (Park & others, 2020). Another study revealed that middle-aged adults who engaged in active leisure-time pursuits had a higher cognitive performance in late adulthood (Ihle & others, 2015). Further, a recent study found that middle-aged and older adult women who engaged in a higher level of leisure-time physical activity were more likely to report experiencing positive emotions (Holahan & others, 2020). Also, a recent European study of middle-aged adults revealed that the more they engaged in physical activity in their leisure time, the less likely they were to be depressed (Marques & others, 2020). And a recent study indicated that the more individuals engaged in leisure-time physical activity, the less work-related stress they had (Du Prel, Siegrist, & Borchart, 2019).

Adults at midlife need to begin preparing psychologically for retirement. Participating in constructive and fulfilling leisure activities in middle adulthood is an important part of this preparation. If adults develop leisure activities that they can continue into retirement, the transition from work to retirement can be less stressful.

4 Aging and the Social World

LG4 Summarize the social aspects of aging.

Social Theories of Aging | Stereotyping of Older Adults | Social Support and Social Integration | Successful Aging

What happens to our social world when we get older? Does it shrink? Do we become more selective and spend more time with our closest friends? How do social experiences influence the aging process? In this section we'll explore some theories of aging that emphasize the role of social experiences.

developmental **connection**

Social Contexts

Socioemotional selectivity theory also focuses on the types of goals individuals are motivated to achieve as they go through the adult years. Connect to "Emotional Development and Attachment."

SOCIAL THEORIES OF AGING

Socioemotional selectivity theory states that motivation changes as a function of time horizons. When time horizons are limited, there is a shift toward prioritizing emotional meaning and satisfaction. One explanation for prioritizing meaningful relationships when getting older is the increasingly limited time left in life (Moss & Wilson, 2018). The priority placed on meaning is associated with greater selectivity about social networks as adults grow older. Researchers have found extensive support for socioemotional selectivity theory (Carstensen, 2019; Carstensen & DeLiema, 2018). Let's consider two other social theories of aging next.

Disengagement theory states that to cope effectively, older adults should gradually withdraw from society. This theory was proposed half a century ago (Cumming & Henry, 1961). In this view, older adults develop increasing self-preoccupation, lessen emotional ties with others, and show decreasing interest in society's affairs. By following these strategies of disengagement, it was thought that older adults would enjoy enhanced life satisfaction. This theory generated a storm of protest and met with a quick death. We present it because of its historical relevance. Although not formally proposed until 1961, it summarized the prevailing beliefs about older adults in the first half of the twentieth century.

Activity theory states that the more active and involved older adults are, the more satisfied they will be with their lives. Thus, activity theory is the exact opposite of disengagement theory. Researchers have found strong support for activity theory, beginning in the 1960s and continuing into the twenty-first century (Peven, Stillman, & Erickson, 2020). One longitudinal study found that a higher overall activity level (which included social activities such as visiting relatives or friends, solitary activities such as hobbies, and productive activities such as volunteer work and gardening) at the beginning of the study was related to greater happiness, better physical and cognitive functioning, and reduced mortality six years later (Menec, 2003). Another study found that older adults who increased their leisure-time activity were three times more likely to have a slower progression to functional disability (Chen & others, 2016). And a recent study indicated that an activity-based lifestyle was linked to lower levels of depression in older adults (Juang & others, 2018). In sum, when older adults are active, energetic, and productive, they age more successfully and are happier than if they disengage from society (Wang & others, 2020).

Photographer Li Yuzhen is 105 years old and still works in a photo studio in Lianhua, China. *How does this centenarian's behavior contradict negative stereotyping of older adults?*
Imagine China/Newscom

STEREOTYPING OF OLDER ADULTS

Social participation by older adults is often discouraged by **ageism,** which is prejudice against others because of their age, especially prejudice against older adults (Airth & Oelke, 2020). Older adults are often perceived as incapable of thinking clearly, learning new things, enjoying sex, contributing to the community, or holding responsible jobs (Senger, 2019). Because of their age, older adults might not be hired for new jobs or might be eased out of old ones; they might be shunned socially; and they might be edged out of their family life.

Ageism is widespread (Lytle, Nowacek, & Levy, 2020). One study found that men were more likely to negatively stereotype older adults than were women (Rupp, Vodanovich, & Crede, 2005). Research indicates that the most frequent form of ageism is disrespect for older adults, followed by assumptions about ailments or frailty caused by age (Palmore, 2004). Also, a recent study conducted in 29 European countries examined age discrimination by individuals 15 to 115 years of age (Bratt & others, 2018). In this study, younger individuals showed more age

disengagement theory The theory that, to cope effectively, older adults should gradually withdraw from society; this theory is not supported by research.

activity theory The theory that the more active and involved older adults are, the more likely they are to be satisfied with their lives.

ageism Prejudice against people because of their age, especially prejudice against older adults.

discrimination toward older adults than did older individuals. And a recent research review on older adults' health in 45 countries concluded that ageism led to worse health outcomes, especially in less-developed countries and among those with less education (Chang & others, 2020).

With the COVID-19 pandemic has come an increase in ageism. A recent analysis concluded that people over 70 years of age are increasingly described as helpless, frail, and unable to contribute to society (Ayalon & others, 2021). Such overgeneralizations are harmful and contradict the heterogeneous nature of aging and the continuing contributions older adults make to society

SOCIAL SUPPORT AND SOCIAL INTEGRATION

Social support and social integration play important roles in the physical and mental health of older adults (Gu & others, 2020). In the *social convoy* model of social relations, individuals go through life embedded in a personal network of individuals to whom they give, and from whom they receive, social support (Antonucci & Webster, 2019). Social support can help individuals of all ages cope more effectively with life's challenges.

For older adults, social support is related to their physical and mental health as well as their life satisfaction (Ponce de Leon, Mangin, & Ballesteros, 2020; Sachs-Ericsson & others, 2021). It is linked with a reduction in symptoms of disease, with the ability to meet one's own health-care needs, and increased longevity (Kong & others, 2019). In a recent meta-analysis of Chinese older adults, low levels of social support were linked to higher rates of depression, and higher levels of social support were linked to lower rates of depression (Qiu & others, 2020). Further, one study revealed that older adults who experienced a higher level of social support showed later cognitive decline than their counterparts who received lower levels of social support (Dickinson & others, 2011).

What characterizes social integration in the lives of older adults?
Yellow Dog Productions/Getty Images

Social integration also plays an important role in the lives of many older adults (Torrejon & Martin-Matthews, 2021). One study found that older adults with higher levels of social integration were less depressed (Ivan Santini & others, 2015). Also, a recent study found that loneliness and lack of social integration were linked to increased suicidal ideation in single older men (Lutzman, Sommerfeld, & Ben-David, 2020). And a recent study of older adults found that interactions involving a greater variety of social ties were associated with engaging in more physical activity and less sedentary time (Fingerman & others, 2020). Also in this study, greater involvement with diverse social ties was linked to having more positive mood.

Researchers have found that older adults tend to report being less lonely than younger adults and less lonely than would be expected based on their circumstances (Schnittker, 2007). Their reports of feeling less lonely than younger adults likely reflect their more selective social networks and greater acceptance of spending time alone (Antonucci & Webster, 2019). In one study, the most consistent factor that predicted loneliness in older adults at 70, 78, and 85 years of age was not being married (Stessman & others, 2014). In other research with 60- to 80-year-olds, the partner's death was a stronger indicator of loneliness for men than for women (Nicolaisen & Thorsen, 2014). And in a recent study, 18 percent of older adults stated they were often or frequently lonely (Due, Sandholdt, & Waldorff, 2017). In this study, the most important predictors of feeling lonely were anxiety and depressive symptoms, living alone, and low social participation.

SUCCESSFUL AGING

On a number of occasions, we have called attention to the positive aspects of aging. In fact, examining the positive aspects of aging is an important trend in life-span development and is likely to benefit future generations of older adults (Salamene & others, 2021).

There are many robust, healthy older adults. With a proper diet, an active lifestyle, mental stimulation and flexibility, positive coping skills, good social relationships and support, and the absence of disease, many abilities can be maintained or in some cases even improved as

we get older (Fingerman & others, 2020). Even when individuals develop a disease, improvements in medical technology mean that increasing numbers of older adults can continue to lead active, constructive lives (Gyasi, Abass, & Adu-Gyamfi, 2020). A Canadian study found that the predicted self-rated probability of aging successfully was 41 percent for those 65 to 74, 33 percent for those 75 to 84, and 22 percent for those 85 years of age and older (Meng & D'Arcy, 2014). In this study, being younger, married, a regular drinker, healthy, and satisfied with life were associated with successful aging. Presence of disease was linked to a significant decline in successful aging. Having selective positive family and friendship relationships is associated with successful aging (Carstensen, 2015, 2016, 2019). And in a recent study, the following four factors characterized successful aging: proactive engagement, wellness resources, positive spirit, and valued relationships (Lee, Kahana, & Kahana, 2017).

Being active is especially important to successful aging (Lee & others, 2020; Phulkerd & others, 2021). Older adults who exercise regularly, attend meetings, participate in religious activities, and go on trips are more satisfied with their lives than their counterparts who disengage from society (Herda & others, 2020). Older adults who engage in challenging cognitive activities are more likely to retain their cognitive skills for a longer period of time (Bae & Kim, 2021; Wu & Rebok, 2020). Older adults who are emotionally selective, optimize their choices, and compensate effectively for losses increase their chances of aging successfully (Nimrod, 2020). And a very important agenda for researchers is to continually improve our understanding of how people can live longer, healthier, more productive and satisfying lives (Rogers, Blocker, & Dupuy, 2020; van Oort & others, 2021).

Laura Carstensen (2015, 2016, 2019) has described the challenges and opportunities involved in the dramatic increase in life expectancy that has been occurring and continues to occur. In her view, the remarkable increase in the number of people living to older ages has occurred in such a short time that science, technology, and behavioral adaptations have not kept pace. She proposes that the challenge is to change a world constructed mainly for young people to a world that is more compatible and supportive for the increasing number of people living to age 100 and older.

In further commentary, Carstensen (2015, p. 70) remarked that achieving this transformation would be no small feat:

> . . . parks, transportation systems, staircases, and even hospitals presume that the users have both strength and stamina; suburbs across the country are built for two parents and their young children, not single people, multiple generations, or elderly people who are not able to drive. Our education system serves the needs of young children and young adults and offers little more than recreation for experienced people.

Indeed, the very conception of work as a full-time endeavor ending in the early sixties is ill suited for long lives. Arguably the most troubling is that we fret about ways the older people lack the qualities of younger people rather than exploit a growing new resource right before our eyes: citizens who have deep expertise, emotional balance, and the motivation to make a difference.

Ninety-year-old Warren Buffett, one of the world's richest individuals, continues to have a very active and successful life. He has donated more than $30 billion to several foundations, with the bulk of the money given to the Bill and Melinda Gates Foundation, which plans to use it to reduce poverty, improve education, and solve health problems.

5 Sociocultural Influences

LG5 Evaluate sociocultural influences on development.

Culture | Socioeconomic Status and Poverty | Ethnicity

Personal relations with friends and other peers form only part of the social world outside the family that influences development. As we have seen throughout this book, development is also influenced by sociocultural contexts. Here we take a closer look at three aspects of those contexts: culture, socioeconomic status, and ethnicity.

What is culture? How does it influence people's lives?
DistinctiveImages/Getty Images

culture The behavior, patterns, beliefs, and all other products of a group of people that are passed on from generation to generation.

cross-cultural studies Studies that compare aspects of two or more cultures to provide information about the degree to which development is similar or universal across the cultures, or is instead culture-specific.

CULTURE

Culture refers to the behavior, patterns, beliefs, and all other products of a group of people that are passed on from generation to generation. It results from the interaction between people and their environment over many years (Landis & Bhawuk, 2021). Everyone has a culture. For example, one person might be a first-generation Latinx immigrant; another might be a third-generation African American; yet another might be a fifth-generation non-Latinx White Texan; and yet another might have a culture that is a mixture of two more ethnic/cultural backgrounds.

Cross-cultural studies compare aspects of two or more cultures, providing information about the degree to which development is similar, or universal, across cultures, or is instead culture-specific (Kallschmidt & others, 2021). One study revealed that from the beginning of seventh grade through the end of eighth grade, U.S. adolescents valued academics less and their motivational behavior also decreased (Wang & Pomerantz, 2009). By contrast, the value placed on academics by Chinese adolescents did not change across this time frame and their motivational behavior was sustained. In the chapter on "Schools, Achievement, and Work," we discuss in greater detail the higher math and science achievement of Asian children in comparison with U.S. children.

The concept of culture is broad; it includes many components and can be analyzed in many ways (Draguns & Tanaka-Matsumi, 2021). Cross-cultural expert Richard Brislin (1993) described a number of characteristics of culture:

- Culture is made up of ideals, values, and assumptions about life that guide people's behavior.
- Culture consists of those aspects of the environment that people make.
- Culture is transmitted from generation to generation, with responsibility for the transmission resting on the shoulders of parents, teachers, and community leaders.
- When their cultural values are violated or their cultural expectations are ignored, people react emotionally.
- It is not unusual for people to accept a cultural value at one point in their lives and reject it at another point. For example, rebellious adolescents and young adults might accept a culture's values and expectations after having children of their own.

Classical research by American psychologist Donald Campbell and his colleagues (Brewer & Campbell, 1976; Campbell & LeVine, 1968) revealed that people in all cultures tend to do the following things:

- think that what happens in their culture is "natural" and "correct" and that what happens in other cultures is "unnatural" and "incorrect";
- perceive their cultural customs as universally valid—that is, conclude that "what is good for us is good for everyone";
- behave in ways that favor their cultural group; and
- feel hostile toward other cultural groups.

In other words, people in all cultures tend to display **ethnocentrism,** the tendency to consider one's own group superior to others.

The Relevance of Culture for the Study of Life-Span Development

Global interdependence is an inescapable reality (Fontaine, 2021). Children, adolescents, and adults

are not just citizens of one country; they are citizens of the world—a world that, through advances in transportation and technology, has become increasingly connected. By better understanding cultures around the world, we may be able to interact more effectively with each other and make this planet a more hospitable, peaceful place (Bhawuk & Landis, 2021).

Individualism and Collectivism What cultural differences are significant in life-span development? One finding in cross-cultural research is that cultures around the world tend to take two very different orientations to life and social relations (Bhawuk & Bhawuk, 2021). That is, cultures tend to emphasize either individualism or collectivism:

- **Individualism** involves giving priority to personal goals rather than to group goals; it emphasizes values that serve the self, such as feeling good, obtaining personal distinction through achievement, and preserving independence.
- **Collectivism** emphasizes values that serve the group by subordinating personal goals to preserve group integrity, supporting interdependence of the members, and promoting harmonious relationships.

Figure 6 summarizes some of the main characteristics of individualistic and collectivistic cultures. Many Western cultures, such as those of the United States, Canada, Great Britain, and the Netherlands, are described as individualistic; many Eastern cultures, such as those of China, Japan, India, and Thailand, are described as collectivistic (Kulich & others, 2021). However, a study conducted from 1970 to 2008 found that although China continued to be characterized by collectivistic values, the frequency of words used in China to index individualistic values had increased (Zeng & Greenfield, 2015). Also, a recent study of African American and non-Latinx White elementary school students found that African American children had higher levels of individualism (Smith & others, 2019). Also in this study, children with collectivistic values engaged less in delinquent behaviors, while those with individualistic values showed less prosocial behavior and had more conduct issues.

Individualistic	Collectivistic
Focuses on individual.	Focuses on groups.
Self is determined by personal traits independent of groups; self is stable across contexts.	Self is defined by in-group terms; self can change with context.
Private self is more important.	Public self is most important.
Personal achievement, competition, power are important.	Achievement is for the benefit of the in-group; cooperation is stressed.
Cognitive dissonance is frequent.	Cognitive dissonance is infrequent.
Emotions (such as anger) are self-focused.	Emotions (such as anger) are often relationship based.
People who are the most liked are self-assured.	People who are the most liked are modest, self-effacing.
Values: pleasure, achievement, competition, freedom.	Values: security, obedience, in-group harmony, personalized relationships.
Many casual relationships.	Few, close relationships.
Save own face.	Save own and other's face.
Independent behaviors: swimming, sleeping alone in room, privacy.	Interdependent behaviors: co-bathing, co-sleeping.
Relatively rare mother-child physical contact.	Frequent mother-child physical contact (such as hugging, holding).

FIGURE **6**
CHARACTERISTICS OF INDIVIDUALISTIC AND COLLECTIVISTIC CULTURES.

Many of the assumptions about contemporary ideas in fields like life-span development were developed in individualistic cultures (Triandis, 2007). Consider the flurry of self-terms in psychology that have an individualistic focus: *self-actualization, self-awareness, self-efficacy, self-reinforcement, self-criticism, self-serving, selfishness*, and *self-doubt* (Lonner, 1988).

Self-conceptions are related to culture. In one study, American and Chinese college students completed 20 sentences beginning with "I am" (Trafimow, Triandis, & Goto, 1991). As indicated in Figure 7, the American college students were much more likely than the Chinese students to describe themselves with personal traits ("I am assertive," for example), rather than identify themselves by their group affiliations ("I am a member of the math club," for example). However, researchers found that from 1990 to 2007, Chinese 18- to 65-year-olds increasingly included more individualistic characteristics in their descriptions of what constitutes happiness and well-being (Steele & Lynch, 2013). Likewise, a recent research review concluded that individualism is rising in Japan (Ogihara, 2017). These increases in individualism in Japan include stronger individualistic values and standards in the workplace and schools, parents giving more individualistic names to their children, and more frequent appearance of words such as "individual" and "uniqueness" in the media.

Some social scientists note that many problems in Western cultures are intensified by the Western cultural emphasis on individualism (Ibrahim, 2021). The rates of suicide, drug abuse, crime, teenage pregnancy, divorce, child abuse, and mental disorders are higher in individualistic cultures than in collectivistic ones. A study across 62 countries found that reported student aggressive behavior for fourth- and eighth-graders was higher in individualistic countries than in collectivistic cultures (Bergmuller, 2013).

ethnocentrism The tendency to consider one's own group superior to other groups.

individualism Giving priority to personal goals rather than to group goals; emphasizing values that serve the self, such as feeling good, obtaining personal distinction through achievement, and preserving independence.

collectivism Emphasizing values that serve the group by subordinating personal goals to preserve group integrity, supporting interdependence of members, and promoting harmonious relationships.

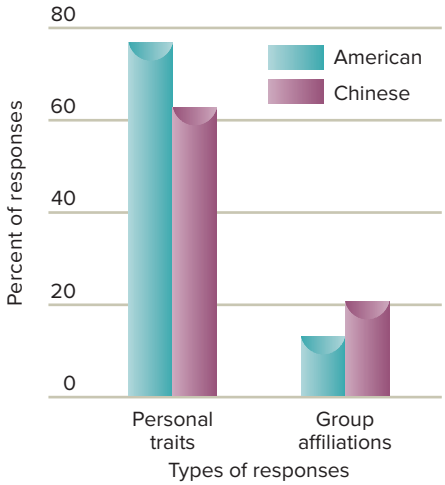

FIGURE 7

AMERICAN AND CHINESE SELF-CONCEPTIONS. College students from the United States and China completed 20 "I am" sentences. Both groups filled in personal traits more than group affiliations. However, the Chinese students filled in the blanks with group affiliations more often than the U.S. students did.

Critics of the concept of individualistic and collectivistic cultures argue that these terms are too broad and simplistic, especially with globalization increasing (Sugimura & Mizokami, 2012). Regardless of their cultural background, people need both a positive sense of self and connectedness to others to develop fully as human beings. Carolyn Tamis-LeMonda and her colleagues (2008) emphasize that in many families, children are not reared in environments that uniformly endorse either individualistic or collectivistic values, thoughts, and actions. Rather, in many families, children are "expected to be quiet, assertive, respectful, curious, humble, self-assured, independent, dependent, affectionate, or reserved depending on the situation, people present, children's age, and social-political and economic circles." Nonetheless, a number of studies continue to find differences between individualistic and collectivistic cultures in a number of areas (Germani & others, 2021; Masuda & others, 2020).

Media/Screen Time If the amount of time spent in an activity is any indication of its importance, there is no doubt that media viewing and screen time play important roles in children's and adolescents' lives (Maloy & others, 2021). Few developments in society in the second half of the twentieth century had a greater impact on children than television. Television continues to have a strong influence on children's development, but children's use of other media and information/communication devices has led to the use of the term *screen time*, which encompasses the total amount of time individuals spend watching television or DVDs, playing video games, and using computers or mobile media such as smartphones (Boers, Afzali, & Conrod, 2020; Kolovos & others, 2021). Recently the World Health Organization (WHO) recommended that 3- to 4-year-olds should engage in no more than 1 hour of sedentary screen time daily (Willumsen & Bull, 2020). In a recent study, 3- to 4-year-old African American children and children who lived at or below the poverty level were more likely than other children to engage in more than 1 hour of screen time daily (Kracht, Webster, & Staiano, 2020).

Among the concerns about children having so much screen time are decreasing time spent in play, less time interacting with peers, decreased physical activity, increased risk of being overweight or obese, poor sleep habits, higher rates of aggression, and lower academic performance (Friel & others, 2020). For example, a recent study of 11,000 9- to 10-year-old children found that higher levels of screen time were linked to shorter sleep duration, later sleep onset, and more sleep disturbances (Hisler & others, 2020). Further, a study of Canadian youth found that higher levels of screen time were linked to higher rates of depression and anxiety (Maras & others, 2015). Also, in a recent study of preschool children, compared with children with less than 30 minutes of screen time per day, those with 2 or more hours per day were much more likely to have inattention problems (including a higher risk of developing ADHD symptoms) and externalizing problems (Tamana & others, 2019). Further, a recent study revealed that less screen time was associated with adolescents having a better quality of life (Yan & others, 2017). In addition, a recent study of Japanese elementary school students revealed that longer screen time duration was linked to increased obesity, decreased physical activity, and lower academic performance (Mineshita & others, 2021). And a recent Dutch study indicated that children were less physically active and screen time was much higher during and after school closures during the COVID-19 pandemic lockdown (Ten Velde & others, 2021).

To better understand various aspects of U.S. children's and adolescents' media use/screen time, the Kaiser Family Foundation funded national surveys in 1999, 2004, and 2009. The 2009 survey included more than 2,000 8- to 18-year-olds and documented that children's and adolescents' media use had increased dramatically in recent years (Rideout, Foehr, & Roberts, 2010). Today's youth live in a world in which they are encapsulated by media. In this survey, in 2009, 8- to 11-year-olds used media 5 hours and 29 minutes a day, but 11- to 14-year-olds used media an average of 8 hours and 40 minutes a day and 15- to 18-year-olds an average of 7 hours and 58 minutes a day (see Figure 8). Thus, daily media use jumps by more than 3 hours in early adolescence. The largest increases in media use in early adolescence are for TV viewing and video gaming. TV use by youth increasingly has involved watching TV on the Internet via a PC, notebook computer, or smartphone. As indicated in Figure 8, time spent listening to music and using computers also increases considerably among 11- to 14-year-old adolescents. Based on the

2009 survey, adding up the daily media use figures to obtain weekly media use leads to the staggering levels of more than 60 hours a week of media use by 11- to 14-year-olds and almost 56 hours a week by 15- to 18-year-olds.

Are there gender differences in digital media use? In recent research on 13- to 18-year-olds in the United States and the United Kingdom, adolescent girls spent more time on smartphones, social media, texting, general computer use, and being online while boys spent more time engaging in gaming and on electronic devices in general (Twenge & Martin, 2020). For both girls and boys, heavy users of digital media were twice as likely as low users to have low psychological well-being and mental health issues.

A major trend in the use of technology is the dramatic increase in media multitasking (Maloy & others, 2021). In one survey, 51 percent of adolescents reported that they "often" or "sometimes" watched TV or use social media (50 percent) while doing homework and even more said the same thing about texting (60 percent) and listening to music (76 percent) (Common Sense Media, 2015). Almost two-thirds of adolescents indicated that they did not think that watching TV (63 percent), texting (64 percent), or using social media (55 percent) while doing homework made any difference in the quality of their work.

What are some outcomes when adolescents frequently engage in media multitasking? In a research review, a higher level of media multitasking was linked to lower levels of school achievement, executive function, and growth mindset in adolescents (Cain & others, 2016). Further, in a recent study of 11- to 18-year-olds in Spain, media multitasking during homework was linked to lower executive function, a lower level of working memory, and worse academic performance in language and math (Martin-Perina, Vinas Poch, & Malo Cerrato, 2019). In another study, heavy media multitaskers were more likely to be depressed and have social anxiety than their counterparts who engaged in media multitasking less heavily (Becker, Alzahabi, & Hopwood, 2013). In addition, a recent study found that media multitasking was linked to a higher risk for obesity and increased responsiveness to rewarding food stimuli (Lopez, Heatherton, & Wagner, 2020). Portable electronic devices, such as smartphones, are mainly driving the increased media use by adolescents (O'Reilly, 2020).

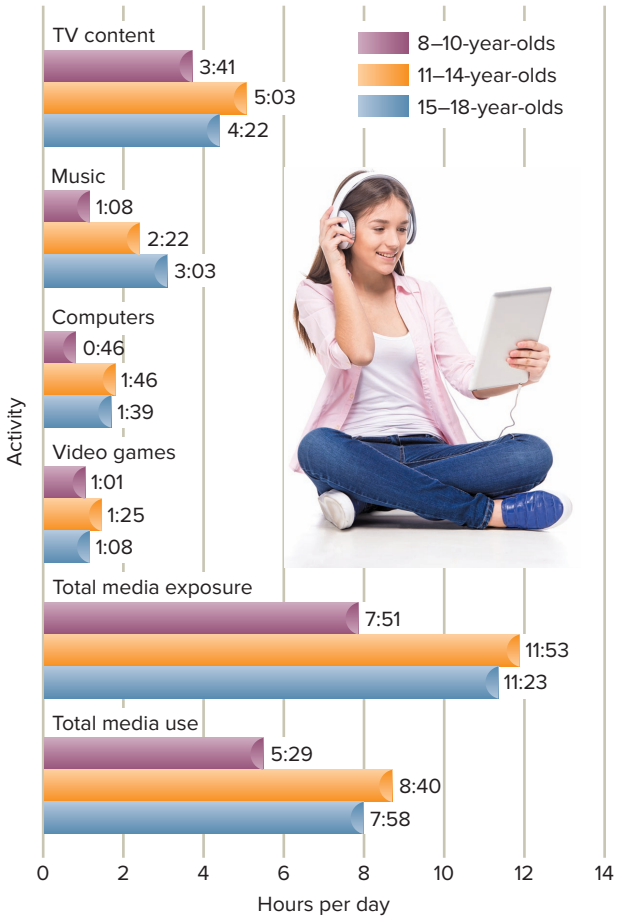

FIGURE **8**

DEVELOPMENTAL CHANGES IN THE AMOUNT OF TIME U.S. 8- TO 18-YEAR-OLDS SPEND WITH DIFFERENT TYPES OF MEDIA.

Television Many children spend more time watching television than they spend interacting with their parents. Although it is only one of the many mass media that affect children's behavior, television may be the most influential. The persuasive capabilities of television are staggering. The 20,000 hours of television watched by the time the average American adolescent graduates from high school are greater than the number of hours spent in the classroom.

Television can have positive or negative effects on children's and adolescents' development. Television can have a positive influence by presenting motivating educational programs, expanding children's and adolescents' information about the world beyond their immediate environment, and providing models of prosocial behavior (Maloy & others, 2021).

Some types of TV shows are linked to positive outcomes for children. For example, a recent meta-analysis found that children's exposure to prosocial media is linked to higher levels of prosocial behavior and empathetic concern (Coyne & others, 2018). And a meta-analysis of studies in 14 countries found positive outcomes for watching the TV show *Sesame Street* in three areas: cognitive, learning about the world, and social reasoning and attitudes toward outgroups (Mares & Pan, 2013).

However, television can have a negative influence on children and adolescents by making them passive learners, distracting them from doing homework, teaching them stereotypes, providing them with violent models of aggression, and presenting them with unrealistic views of the world (Hogan & Strasburger, 2020). Further, researchers have found that higher levels of TV viewing are linked to higher rates of obesity in children and adolescents (Guo & others, 2020).

The extent to which children and adolescents are exposed to violence and aggression on television raises special concerns (Khurana & others, 2019). In a study of children, greater exposure to TV violence, video game violence, and music video violence was independently associated with a higher level of physical aggression (Coker & others, 2015).

How might playing violent video games be related to adolescent aggression?

How much screen time is recommended for young children?
Luca Cappelli/Getty Images

Video Games Violent video games, especially those that are highly realistic, also raise concerns about their effects on children and adolescents (Mohammadi & others, 2020). In a recent research review, it was concluded that children and adolescents who extensively play violent electronic games are more aggressive and engage in less prosocial behavior than their counterparts who spend less time playing the games or do not play them at all (Anderson & others, 2018).

Media/Screen Time, Learning, and Children's Development
The effects of media/screen time on children depend on how old children are and the type of media involved. A research review reached the following conclusions about media/screen viewing by infants and young children (Kirkorian, Wartella, & Anderson, 2008):

- *Infancy.* Learning from media is difficult for infants and toddlers, and they learn much more easily from direct experiences with people.
- *Early childhood.* At about 3 years of age, children can learn from media with educational material if the media use effective strategies such as repeating concepts a number of times, use images and sounds that get young children's attention, and use children's rather than adults' voices. However, the vast majority of media that young children experience is geared toward entertainment rather than education.

The American Academy of Pediatrics (2001) recommends that children under 2 years of age not watch television because doing so is likely to reduce direct interactions with parents. One study found that the greater the number of hours of TV viewed per day by 1- and 3-year-olds, the more likely they were to have attention problems at 7 years of age (Christakis & others, 2004), and another study also revealed that daily TV exposure at 18 months was linked to increased inattention/hyperactivity at 30 months of age (Cheng & others, 2010). Also, a study of 2- to 48-month-olds indicated that each hour of audible TV was linked to a reduction in child vocalizations (Christakis & others, 2009), and another study revealed that 8- to 16-month-olds who viewed baby DVDs/videos had poor language development (Zimmerman, Christakis, & Meltzoff, 2007). Further, a recent study of 18-month-olds revealed that screen media multitasking at 18 months of age was linked to having more behavioral problems and a lower level of cognitive functioning at 4 to 6 years of age (Srisinghasongkram & others, 2020).

Higher levels of parental monitoring of children's media use have been linked to a number of positive outcomes (more sleep, better school performance, less aggressive behavior, and more prosocial behavior) (Barr, 2019). Further, a recent study indicated that parental monitoring of media violence exposure was linked to less aggressive behavior in adolescents (Khurana & others, 2019).

The more time that children and adolescents spend watching TV, the lower their school achievement (Comstock & Scharrer, 2006). For example, a research review concluded that higher levels of screen time (mostly involving TV viewing) were associated with lower levels of cognitive development in early childhood (Carson & others, 2015). In a recent study of adolescents, increased screen time predicted lower academic achievement in English and math (Hunter, Leatherdale, & Carson, 2018).

Technology and Digitally Mediated Communication Culture involves change, and nowhere is that change greater than in the technological revolution individuals are experiencing with increased use of computers and the Internet (Maloy & others, 2021). Society still relies on some basic nontechnological competencies—for example, good communication skills, positive attitudes, and the ability to solve problems and to think deeply and creatively. But how people pursue these competencies is changing in new ways and at a speed that few people had to cope with in previous eras. For youth to be adequately prepared for tomorrow's jobs, technology needs to become an integral part of their lives.

The digitally mediated social environment of youth includes e-mail, text messaging, social networking sites such as Facebook, chat rooms, videosharing and photosharing, multiplayer online computer games, and virtual worlds. Most of these digitally mediated social interactions began on computers but more recently have also shifted to smartphones. For example, in 2004,

39 percent of adolescents owned a smartphone, a figure that jumped to 66 percent in 2009 and then to 95 percent in 2018 (Anderson & Jiang, 2018). Also, in a 2019 survey of 18- to 24-year-olds, 90 percent reported using YouTube, 76 percent Facebook, 75 percent Instagram, and 73 percent Snapchat (Perrin & Anderson, 2019). Further, a large-scale study of more than 32,000 15-year-olds in 37 countries found that problematic social media and low social support were the strongest predictors of low life satisfaction (Walsh & others, 2020).

Text messaging has now become the main way that adolescents connect with their friends, surpassing face-to-face contact, e-mail, instant messaging, and voice calling (Lenhart, 2015a). A survey of 12- to 17-year-olds found that they sent an average of 55 text messages per day (Lenhart, 2015b). A special concern is *sexting,* which involves sending sexually explicit images, videos, or text messages via electronic communication.

Concerns have emerged about children's and adolescents' access to information on the Internet, which has been largely unregulated. Youth can access pornography, instructions for making bombs, Web sites of hate groups and conspiracy theorists, and other material that is inappropriate for them. Clearly, parents need to monitor and regulate adolescents' use of the Internet.

What characterizes the online social environment of adolescents?
Anne Ackermann/Digital Vision/Alamy Stock Photo

The Internet and Aging Adults The Internet plays an increasingly important role in providing access to information and communication for adults as well as youth (Fields & others, 2020; Macdonald & Hulur, 2021). In 2019, 73 percent of U.S. adults 65 years of age and over were using the Internet, up from 59 percent in 2013 and 14 percent in 2000 (Anderson & others, 2019). Increasing numbers of older adults use e-mail and smartphones to communicate, especially with friends and relatives (Gillain & others, 2019).

How is Internet use linked to various aspects of older adults' lives? A longitudinal study revealed that Internet use by older adults reduced their likelihood of being depressed by one-third (Cotten & others, 2014). Also, in a recent study of older adults, having an iPad strengthened their family ties and brought a greater sense of overall connection to society (Delello & McWhorter, 2017). In addition, a recent study of older adults revealed that increased Internet use was associated with decreased loneliness (Yu, Wu, & Chi, 2021). Further, in a recent Hong Kong study, adults 75 and older who used smartphones and the Internet to connect with family, friends, and neighbors had a higher level of psychological well-being than their counterparts who did not use this technology (Fang & others, 2018). And as with children and younger adults, cautions about verifying the accuracy of information—especially on topics involving medical conditions—on the Internet should always be kept in mind (Arcury & others, 2020).

Are older adults keeping up with changes in technology?
Sami Sarkis/Getty Images

Although computers, smartphones, and the Internet are now playing more important roles in the lives of people of all ages, people continue to watch extensive amounts of television, especially in late adulthood. In a 2016 Nielsen survey, adults age 65 and older watched television an average of 51 hours, 32 minutes per week (Recode, 2016). That 51+ hours per week is far more than the averages for other age groups: 25 to 34 years (23 hours, 26 minutes), 35 to 49 years (32 hours, 7 minutes), and 50 to 64 years (44 hours, 6 minutes). The staggering number of hours older adults watch television each week raises concerns about how such lengthy sedentary behavior might interfere with participating in physical exercise and interacting with others—activities that are linked to physical and emotional well-being.

Aging and Culture Culture plays an important role in aging (Beller & Wagner, 2020). What promotes a good old age in most cultures? What factors are associated with whether older adults are accorded a position of high status in a culture? Seven factors are most likely to predict high status for the elderly in a culture (Sangree, 1989):

- Older persons possess valuable knowledge.
- Older persons control key family/community resources.
- Older persons are permitted to engage in useful and valued functions as long as possible.
- There is role continuity throughout the life span.
- Age-related role changes involve greater responsibility, authority, and advisory capacity.
- The extended family is a common family arrangement in the culture, and the older person is integrated into the extended family.

Cultures differ in the amount of prestige they give to older adults. In Navajo culture, older adults are especially treated with respect because of their wisdom and extensive life experiences. *What are some other factors that are linked with respect for older adults in a culture?*
meunierd/Shutterstock

In general, respect for older adults is greater in collectivistic cultures (such as China and Japan) than in individualistic cultures (such as the United States). However, some researchers are finding that this collectivistic/individualistic difference in respect accorded to older adults is not as strong as it used to be and that in some cases older adults in individualistic cultures receive considerable respect (Antonucci, Vandewater, & Lansford, 2000).

SOCIOECONOMIC STATUS AND POVERTY

Analyzing cultures represents just one way to understand the social context of life-span development. Another approach focuses on inequalities present in every society (van der Hoeven, 2021). That is, how do people in a particular society differ in their access to economic, social, and psychological resources, and how do these differences affect their development through life?

What Is Socioeconomic Status?

Socioeconomic status (SES) refers to a grouping of people with similar occupational, educational, and economic characteristics. Generally, members of a society (1) hold occupations that vary in prestige, with some individuals having more access than others to higher-status occupations; (2) attain different levels of education, with some individuals having more access than others to better education; (3) possess different economic resources; and (4) have different degrees of power to influence a community. These differences go together. That is, people with prestigious occupations tend also to have higher levels of educational attainment, more economic resources, and greater power. These differences in the ability to control resources and to participate in society's rewards produce unequal opportunities for people (van der Hoeven, 2021).

The number of different socioeconomic statuses depends on the community's size and complexity. In most investigators' descriptions of socioeconomic status, two broad categories—low-SES and middle-SES—are used, although as many as five categories are delineated. Sometimes low-SES is described as low-income, working-class, or blue-collar; sometimes middle-SES is described as middle-income, managerial, or white-collar. Examples of low-SES occupations are factory worker and maintenance worker. Examples of middle-SES occupations include managerial and professional careers (doctor, lawyer, teacher, accountant, and so on).

Socioeconomic Variations in Neighborhoods and Families

A parent's SES is likely linked to the neighborhoods in which children live and the schools they attend (Reed & others, 2020). Such variations in neighborhood settings can influence children's adjustment (Magnuson & Duncan, 2019).

socioeconomic status (SES) A grouping of people with similar occupational, educational, and economic characteristics.

Neighborhood crime and isolation have been linked with low self-esteem and psychological distress in children (Kim & others, 2020). Further, schools in low-income neighborhoods have fewer resources than schools in higher-income neighborhoods, and they are likely to have more students with lower achievement test scores, lower rates of graduation, and smaller percentages of graduates going on to college (American Psychological Association, 2020).

What characterizes socioeconomic variations in neighborhoods?
zodebala/Getty Images

In the United States and most other Western cultures, differences have been found in child rearing among different SES groups (Hoff, Laursen, & Tardif, 2002, p. 246):

- Lower-SES parents (1) "are more concerned that their children conform to society's expectations," (2) "create a home atmosphere in which it is clear that parents have authority over children," (3) use physical punishment more in disciplining their children, and (4) are more directive and less conversational with their children.
- Higher-SES parents (1) "are more concerned with developing children's initiative and ability to delay gratification," (2) "create a home atmosphere in which children are more nearly equal participants and in which rules are discussed as opposed to being laid down" in an authoritarian manner, (3) are less likely to use physical punishment, and (4) are less directive and more conversational with their children.

Consequences of SES for Children and Adolescents Children and adolescents from low-SES backgrounds are at risk for experiencing low achievement and emotional problems, as well as lower occupational attainment in adulthood (Acosta & others, 2020). A recent study found that lower SES was associated with less cortical surface in the brain of adolescents as well as less effective working memory (Judd & others, 2020). In this study, the SES factor that was most closely associated with the lower level of brain development of adolescents was less parental education. Further, a recent Chinese study found that the link between low family SES and children's lower academic achievement was especially influenced by less parental involvement in children's schooling (Zhang & others, 2020). Psychological problems such as smoking, depression, and juvenile delinquency, as well as health problems, are also more prevalent among low-SES adolescents than among economically advantaged adolescents (American Psychological Association, 2020). For example, a recent study found that of 13 risk factors, low SES was most likely to be associated with smoking initiation in fifth-graders (Wellman & others, 2018).

SES variations in childhood and adolescence also are linked to adult outcomes. For example, a longitudinal study indicated that lower SES in childhood was associated with lower cognitive function and more cognitive decline in middle and late adulthood (Liu & Lachman, 2019). Also, a recent Australian study revealed that children and adolescents from lower-SES backgrounds were less likely achieve a healthy physical fitness level than their higher-SES counterparts (Peralta & others, 2019). Further, in a longitudinal study, low SES in adolescence was linked to having a higher level of depressive symptoms at age 54 for females (Pino & others, 2018). Also in this study, low-SES females who completed college were less likely to have depressive symptoms at age 54 than low-SES females who did not complete college. And in another longitudinal study, low SES in adolescence was a risk factor for having cardiovascular disease 30 years later (Doom & others, 2017).

Nevertheless, a sizable portion of children from low-SES backgrounds are competent and perform well in school; some perform better than many middle-SES and higher-SES students. When students from low-SES backgrounds earn high grades, it is not unusual to find a parent or parents making special sacrifices to provide the conditions that contribute to academic success.

Up to this point we have focused on the challenges faced by many adolescents from low-income families (Chang & Chiang, 2020). However, Suniya Luthar and her colleagues (Ansary, McMahon, & Luthar, 2012, 2017; Luthar, 2006; Luthar, Crossman, & Small, 2015) found that adolescents from affluent families also face challenges. In her research, adolescents from affluent families are vulnerable to high rates of substance abuse. Also, in the affluent families she has studied, males tend to have more adjustment difficulties than females, with affluent female adolescents being more likely to attain superior levels of academic success. Further, in a recent study of more than 13,000 high school students, those attending schools with more affluent classmates were more likely to use drugs, become intoxicated, and engage in property crime, while those attending poorer schools had more depressive and anxiety symptoms and also engaged in more violent behavior (Coley & others, 2018).

Poverty When sixth-graders in a poverty-stricken area of St. Louis were asked to describe a perfect day, one boy said he would erase the world, then he would sit and think. Asked if he wouldn't rather go outside and play, the boy responded, "Are you kidding, out there?" (Children's Defense Fund, 1992). The world is a dangerous and unwelcoming place for too many of America's children, especially those who live in poverty (Children's Defense Fund, 2019). Some children are resilient and cope with the challenges of poverty without any major setbacks, but too many struggle unsuccessfully (Wilmers, 2021). Each child of poverty who reaches adulthood unhealthy, unskilled, or alienated keeps our nation from being as competent and productive as it could be.

Poverty Rates Children who grow up in poverty represent a special concern (Iotti & Jungert, 2020). In 2018, 16.2 percent (down from 21.1 percent in 2014) of U.S. children under 18 years of age were living in families with incomes below the poverty line, with African American (30.1 percent) and Latinx families (23.7 percent) having especially high rates of poverty (Children's Defense Fund, 2020). In 2018, 8.9 percent of non-Latinx White children were living in poverty. The U.S. figure of 16.2 percent of children and adolescents living in poverty is much higher than figures from other industrialized nations. For example, Canada has a child poverty rate of 9 percent and Sweden has a rate of 2 percent.

Compared with non-Latinx White children and adolescents, ethnic minority children and adolescents are more likely to experience persistent poverty over many years and to live in isolated, poor neighborhoods where social supports are minimal and threats to positive development abundant (Jarrett, 1995) (see Figure 9).

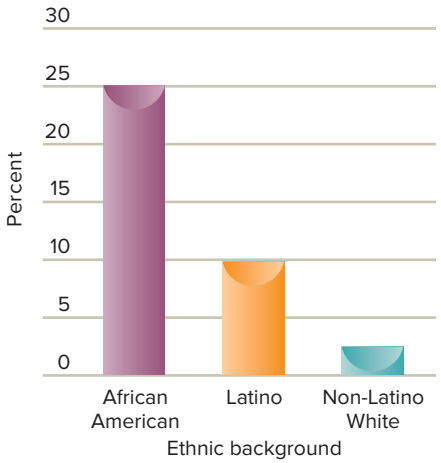

FIGURE **9**

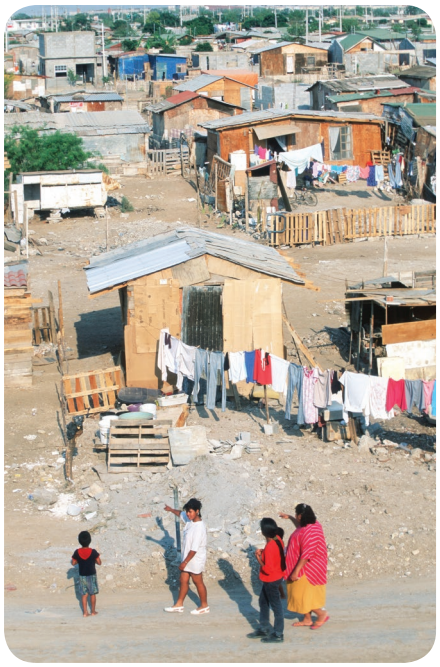
PERCENTAGES OF YOUTH UNDER 18 WHO ARE LIVING IN DISTRESSED NEIGHBORHOODS. *Note*: A distressed neighborhood is defined by high levels (at least one standard deviation above the norm) of (1) poverty; (2) female-headed families; (3) high school dropouts; (4) unemployment; and (5) reliance on public assistance programs.



(*Top*) Children playing in Nueva Era, a low-income area on the outskirts of Nuevo Laredo, Mexico. (*Bottom*) Children who live in an impoverished section of the South Bronx in New York City. *How does poverty affect the development of children like these?*

developmental **connection**
Environment
Reducing the poverty level and improving the lives of children living in poverty are important goals of U.S. social policy. Connect to "Introduction."

feminization of poverty The fact that far more women than men live in poverty. Women's lower income, divorce, infrequent awarding of alimony, and poorly enforced child support by fathers—which usually leave women with less money than they and their children need to adequately function—are the likely causes.

Poverty also is demarcated along educational lines. In 2018, in the United States, for adults living below the poverty line 25.9 percent had no high school diploma, 12.7 percent had a high school diploma but no college attendance, 8.4 percent had some college attendance, and only 4.4 percent had a bachelor's degree or higher (Duffin, 2019).

Psychological Ramifications of Poverty Poor children are often exposed to unhealthful living conditions, inadequate housing and homelessness, less effective schools, environmental toxins, and violence (Suter, Beyacan, & Ravazzini, 2021). What are the psychological ramifications of living in poverty? First, the poor are often powerless. At work, they rarely are the decision makers; rules are handed down to them. Second, the poor are often vulnerable to disaster. They are not likely to be given notice before they are laid off from work, and they usually do not have financial resources to fall back on when problems arise. Third, their alternatives are restricted. Only a limited number of jobs are open to them. Even when alternatives are available, the poor might not know about them or be prepared to make a wise decision because of inadequate education and inability to read well. Fourth, being poor means having less prestige.

One research review concluded that compared with their economically more advantaged counterparts, poor children experience widespread environmental inequities (Evans, 2004). For example, one study found that a higher percentage of children in poor families than in middle-income families were exposed to family turmoil, separation from a parent, violence, crowding, excessive noise, and poor housing (Evans & English, 2002).

Persistent and long-standing poverty can have especially damaging effects on children (Children's Defense Fund, 2020). One study revealed that the more years children spent in poverty, the higher were their physiological indices of stress (Evans & Kim, 2007). Persistent economic hardship as well as very early poverty are linked to lower cognitive functioning in children at 5 years of age (Schoon & others, 2012). Another study revealed that poverty-related adversity in family and school contexts in early childhood was linked to less effective executive function in second and third grades (Cybele Raver & others, 2013).

Feminization of Poverty The term **feminization of poverty** refers to the fact that far more women than men live in poverty (Zhang & Gordon, 2020). A special concern is the high percentage of children and adolescents growing up in mother-headed households in poverty (McLoyd, Hardaway, & Jocson, 2019). In 2019, 34 percent of single-mother families (down from 39.6 percent in 2013) lived in poverty, nearly five times the poverty rate for married-couple families (6 percent) (U.S. Census Bureau, 2019).

Because poor, single mothers are more distressed than their middle-SES counterparts are, they tend to show lower levels of support, nurturance, and involvement with their children. Among the reasons for the high poverty rate of single mothers are women's lower pay, infrequent awarding of alimony payments, and poorly enforced child support by fathers.

Families and Poverty One study documented the important links among economic well-being, parenting behavior, and social adjustment (Mistry & others, 2002). Lower levels of economic well-being and elevated perceptions of economic pressure were linked with parenting behavior. Distressed parents reported feeling less effective and capable in disciplining their children and were observed to be less affectionate in parent-child interactions. In turn, less optimal parenting predicted lower teacher ratings of children's social behavior and higher ratings of behavior problems.

Benefits provided to low-income parents may have positive outcomes for children (Bierman & others, 2021). As described in the "Introduction" chapter, a trend in antipoverty programs is to conduct two-generation interventions (Aspen Institute, 2019). This involves providing services for children and adolescents (such as educational child care, preschool education, or after-school programs for youth) as well as services for parents (such as adult education, literacy training, and job skills training).

Schools and school programs are the focus of some poverty interventions (Nastasi & Naser, 2021). In an intervention with first-generation immigrant children attending high-poverty schools, the City Connects program was successful in improving children's math and reading achievement at the end of elementary school (Dearing & others, 2016). The program is directed by a full-time school counselor or social worker in each school. Annual reviews of children's needs are conducted during the first several months of each school year. Then site coordinators and teachers collaborate to develop a student support plan that might include an

after-school program, tutoring, mentoring, or family counseling. For children identified as having intense needs (about 8 to 10 percent), a wider team of professionals becomes involved, possibly including school psychologists, principals, nurses, and/or community agency staff, to provide additional supports.

Another study assessed the effects of the Positive Action program in 14 urban, low-income Chicago schools across 6 years from grades 3 to 8 (Lewis & others, 2013). The Positive Action program is a K–12 curriculum that focuses on self-concept, self-control and responsibility, physical and mental health, honesty, getting along with others, and continually striving for self-improvement. The program includes teacher, counselor, family, and community training and activities to improve the school-wide atmosphere. In comparison with a control group of schools that did not participate in the Positive Action program, students in the program engaged in a lower rate of violence-related behavior and received fewer disciplinary referrals and suspensions from school.

SES, Poverty, and Aging Another group of special concern consists of older adults who are poor (Nazri, Vanoh, & Leng, 2021). Researchers have found that poverty in late adulthood is linked to an increase in physical and mental health problems (Lubetkin & Jia, 2017). Poverty also is linked to lower levels of physical and cognitive fitness in older adults (Basta & others, 2008). One study found that processing speed was slower in older adults living in poverty (Zhang & others, 2015). And a recent study revealed that poverty increased the risk of earlier death in older adults (Mendonca Guimaraes & Andrade, 2020).

Census data suggest that the overall number of older people living in poverty has declined since the 1960s, but in 2017, 9.2 percent of older adults in the United States were living in poverty (U.S. Census Bureau, 2019). In 2017, U.S. women 65 years and older (10.6 percent) were much more likely to live in poverty than their male counterparts (7.6 percent) (U.S. Census Bureau, 2019). There is a special concern about poverty among older women, especially those who are divorced or never-married, and considerable discussion about the role of Social Security in providing a broad economic safety net for them (Mutchler, Li, & Xu, 2019).

What are some characteristics of older U.S. adults living in poverty conditions?
JerryPDX/Getty Images

ETHNICITY

As our discussion of poverty and aging indicated, differences in SES often overlap with ethnic differences (Banks, 2020). The United States is a showcase for these differences because it has been a magnet for people from many ethnic groups. Cultural heritages from every continent have connected and mixed here (Gollnick & Chinn, 2021). Native Americans, European Americans, African Americans, Latinxs, Chinese Americans, and other groups have retained parts of their culture of origin, lost other parts, and seen some elements transformed as they became part of the mainstream culture.

A special point needs to be made as we explore various aspects of ethnicity. For too long, the prevailing perspective on ethnic differences was deficit-based and assumed that children and adolescents in ethnic minority groups were inherently challenged and overwhelmed by stressors, especially in the case of immigrant ethnic minority adolescents. Countering this perspective is research indicating that ethnic minority adolescents, including those who are immigrants, fare better than expected (Perreira & others, 2019). It is not unusual for adolescents in immigrant families to assume higher levels of responsibility than non-immigrant adolescents and to help their parents adapt to their new society (Halgunseth, 2019).

Immigration Relatively high rates of minority immigration have contributed to growth in the proportion of ethnic minorities in the U.S. population (Khoury & Hakim-Larson, 2021). In 2017, 50.3 percent of children 18 years and younger were non-Latinx White; by 2060, this figure is projected to decrease to 36.4 percent (U.S. Census Bureau, 2019). In 2018, among individuals age 18 and younger in the United States, 25 percent were Latinx, 14 percent were African American, and 5 percent were Asian American. The proportions of ethnic minorities are expected to continue to increase throughout the twenty-first century. Today the United States is more ethnically diverse than ever before. Ninety-three languages are spoken in Los Angeles alone.

Immigrants often experience special stressors (Sidhu & Adam, 2021; Valentin-Cortes & others, 2020). These include language barriers, separation from support networks, changes in SES, health problems, and the challenges of preserving ethnic identity while adapting to the majority culture (Clauss-Ehlers & others, 2021; Romero & others, 2020).

> Consider the flowers of a garden: though differing in kind, color, form, and shape, yet, inasmuch as they are refreshed by the waters of one spring, revived by the breath of one wind, invigorated by the rays of one sun, this diversity increases their charm and adds to their beauty. . . . How unpleasing to the eye if all the flowers and plants, the leaves and blossoms, the fruits, the branches, and the trees of that garden were all the same shape and color! Diversity of hues, form, and shape enriches and adorns the garden and heightens its effect.

Allison Wright/Corbis/Getty Images

Parents and children in immigrant families may be at different stages of *acculturation*, the process of adapting to the majority culture. The result may be conflict over cultural values (Sam, 2018). One study examined values in immigrant (Vietnamese, Armenian, and Mexican) and nonimmigrant families (African American and European American) (Phinney, 1996). In all groups, parents endorsed family obligations more than adolescents did, and the differences between generations generally increased with time spent in the United States. Recently, Yoonsun Choi and her colleagues (Choi & Hahn, 2017; Choi & others, 2020a, b, c) have conducted research with Filipino American and Korean American immigrant families and found the older generation is much more likely than the younger generation to hold on to distinctly traditional values and resist change. She also has discovered that Asian parents are perceived by their children as placing too much emphasis on education.

Ethnicity and Families Families within various ethnic groups in the United States differ in their size, structure, composition, reliance on kinship networks, and levels of income and education (Banks, 2020). Large and extended families are more common among minority groups than among the non-Latinx White majority. For example, 19 percent of Latinx families have three or more children, compared with 14 percent of African American and 10 percent of non-Latinx White families. African American and Latinx children interact more with their grandparents, aunts, uncles, cousins, and more distant relatives than do non-Latinx White children.

Single-parent families are more common among African Americans and Latinxs than among non-Latinx White Americans (U.S. Census Bureau, 2019). In comparison with two-parent households, single parents often have more limited resources of time, money, and energy (Weinraub & Kaufman, 2019). Ethnic minority parents also tend to be less educated and are more likely to live in low-income circumstances than are their non-Latinx White counterparts (McLoyd, Hardaway, & Jocson, 2019). Still, many impoverished ethnic minority families manage to find ways to raise competent children (Magnuson & Duncan, 2019).

Recently immigrated families have had to face special problems (Flores, Okorodudu, & Shepherd, 2021). Many individuals in immigrant families are dealing with the challenges associated with being undocumented. Living in an undocumented family can affect children's developmental outcomes through parents being unwilling to sign up for services for which they may be eligible, unfavorable conditions linked to low-wage work and lack of benefits, increased stress, discrimination, and a lack of cognitive stimulation in the home (Mendez, Flores-Haro, & Zucker, 2020). In a recent study, immigrant children who were once separated from their parents had a lower level of literacy and a higher level of psychological problems than those who had migrated with their parents (Lu, He, & Brooks-Gunn, 2020). Also in this study, a protracted period of separation and prior undocumented status of parents further increased the children's disadvantages.

Poverty contributes to the stressful life experiences of many ethnic minority children (Haft & others, 2020). But even when their families are not poor, economic advantage does not enable ethnic minority children to escape entirely the prejudice and discrimination directed at them. Although middle-SES ethnic minority children have more resources available to counter the destructive influences of prejudice and discrimination, they still cannot completely avoid the pervasive influence of negative stereotypes about ethnic minority groups.

What characterizes families in different ethnic groups in the United States?
Jack Hollingsworth/Ocean/Getty Images

Vonnie McLoyd (1990) concluded that ethnic minority children experience a disproportionate share of the adverse effects of poverty and unemployment in the United States today. Thus, many ethnic minority children experience a double disadvantage: (1) prejudice and discrimination because of their ethnic minority status, and (2) the stressful effects of poverty. Some aspects of home life can help protect ethnic minority children from injustice. The community and the family can filter out destructive racist messages, and parents can present alternative frames of reference to offset those presented by the majority. The extended family also can serve as an important buffer to stress.

Research indicates that many members of families that have recently immigrated to the United States adopt a bicultural orientation, selecting

characteristics of the U.S. culture that help them to survive and advance, while still retaining aspects of their culture of origin (Tikhonova & others, 2019). Immigration also involves cultural brokering, which has increasingly occurred in the United States as children and adolescents serve as mediators (cultural and linguistic) for their immigrant parents (Sim & others, 2019). Further, a study of Asian American adolescents found that a bicultural orientation of both adolescents and their parents enhanced the adolescents' academic achievement (Kim & others, 2015).

In addition to the bicultural orientation involving an ethnic minority individual who lives in a non-Latinx White majority culture, a bicultural orientation also can consist of multi-ethnic individuals, such as an adolescent with an African American and a Latinx heritage or even a mixture of three or more ethnic/racial backgrounds. Research indicates that multi-ethnic/multiracial individuals often face more discrimination and social injustice, often being questioned about their ethnic/racial heritage as well as being more likely to engage in problem behaviors such as substance abuse and violence (Tan & others, 2019; Woo & others, 2020).

Parenting in many ethnic minority families also focuses on issues associated with promoting children's ethnic pride, knowledge of their ethnic group, and awareness of discrimination (Umana-Taylor & Hill, 2020). Researchers are increasingly finding that a positive ethnic identity is related to positive outcomes for ethnic minority adolescents (Umana-Taylor & others, 2020). For example, one study found that Asian American adolescents' positive ethnic identity was associated with high self-esteem, positive relationships, academic motivation, and lower levels of depression over time (Kiang, Witkow, & Champagne, 2013). And in a recent study, Latinx youth showed enhanced resilience against discrimination encounters when they had more family ethnic socialization experiences and engaged in greater ethnic identity exploration and resolution (Martinez-Fuentes, Jager, & Umana-Taylor, 2020).

Many of the families that have immigrated into the United States in recent decades, such as Mexican Americans and Asian Americans, come from collectivistic cultures in which duty to one's family is an important value. Family obligations may include assisting parents in their occupations and contributing to the family's welfare. In a recent study, a higher level of family obligation was linked to Latinx adolescents' higher academic achievement (Anguiano, 2018).

In adopting characteristics of the U.S. culture, Latinx families are increasingly embracing the importance of education (Toyokawa & Toyokawa, 2019). Although their school dropout rates have remained higher than those of other ethnic groups, they declined considerably in the last decade (National Center for Education Statistics, 2020). Ross Parke and his colleagues (2011) have found that Latinx families are retaining a strong commitment to family when they immigrate to the United States despite facing challenges advancing economically. For example, divorce rates for Latinx families are lower than for non-Latinx White families of similar socioeconomic status.

However, there are variations in immigrant Latinx families' experiences and the degree to which their children and adolescents change as they are exposed to American culture (Halgunseth, 2019). One study found that following their immigration, Mexican American adolescents spent less time with their family and identified less with family values (Updegraff & others, 2012). However, in this study, teens with stronger family values in early adolescence were less likely to engage in risky behavior in late adolescence.

Of course, individual families vary, and how successfully ethnic minority families deal with stress depends on many factors (Clauss-Ehlers, Roysircar, & Hunter, 2021). Whether the parents are native-born or immigrants, how long the family has been in the United States, its socioeconomic status, and its national origin all make a difference. The characteristics of the family's social context also influence adaptability. What are the attitudes toward the family's ethnic group within their neighborhood or city? Can the family's children attend good schools? Are there community groups that welcome people from the family's ethnic group? Do members of the family's ethnic group form community groups of their own?

Racism and Discrimination **Racism** is discrimination, prejudice, or antagonism against a person or people based on their race or ethnic group. In 2020, the United States experienced events that drew attention to the dangerous effects of racism and discrimination. The video of the killing of African American George Floyd by a non-Latinx White policeman in Minneapolis led to extensive protests against racism across the United States and around the world. In 2020 and 2021, additional killings of African Americans by non-Latinx White police further ignited anger not just on the part of African Americans but also among non-Latinx Whites and members of other ethnic groups. The deaths of these African Americans convinced many individuals that systemic racism has continued to be extensive in the United

racism Discrimination, prejudice, or antagonism against a person or people based on their racial or ethnic group.

States. Protests against police brutality continued in many cities, both peaceful ones and others that unfortunately sometimes turned into violence and looting of businesses.

These protests against police became associated with a movement called Black Lives Matter. However, the Black Lives Matter movement's goal is not only to protest police brutality against African Americans but also to raise awareness of the lack of opportunities for African Americans to thrive and flourish economically, educationally, and socially. Historically, African Americans have not had adequate access to education, health care, and good jobs, and Black Lives Matter advocates argue that such circumstances are still pervasive. For example, in 2018, the average income of African Americans was $24,700, compared to $42,700 for non-Latinx Whites.

Of course, racism applies not only to discrimination against African Americans but also to discrimination against other ethnic groups such as Latinxs and Asian Americans. Historically, Latinxs, Asian Americans, and other ethnic minority individuals and groups often have faced inadequate access to education, health, good jobs, and other aspects of well-being. As with African Americans, these inequities continue today. For example, in a recent national poll, approximately 40 percent of Latinxs said they had experienced discrimination in 2019, such as being told "Go back to your own country" and being called offensive names (Gonzalez-Barrera & Lopez, 2020). Further, in 2021, there were a number of hate crimes involving physical attacks on Asian Americans.

How should parents talk with their children about racism? Recently, Diane Hughes and her colleagues (Hughes, Fisher, & Cabrera, 2020) proposed the "Intentional Parenting for Equity and Justice" program that emphasizes the importance of having deliberate and purposeful conversations as well as engaging in activities that increase children's awareness of racial inequities and injustices such as systemic racism, racial stereotyping, and the harm caused by racial privilege for those who are excluded. They emphasize that parents should discuss current racial events with their children as much as possible in ways that are aligned with the children's ages and ability to learn. With young children, parents should offer explanations that are simple and brief, shield children from video footage of violence, and be ready to answer children's questions about racial events they may have seen in the media. Conversations with older children and adolescents can include more complex ideas about systemic racism and inequality. Also strongly recommended is to expose children to the accomplishments, rich traditions, and strengths of diverse ethnic and cultural groups. Racial injustice is a problem for everyone, and all parents—not just those from ethnic minority backgrounds—should have these conversations with their children.

In addition, many BIPOC (Black, Indigenous, and other People of Color) parents emphasize how their children and youth can stay safe during interactions with the police. One book that helps BIPOC parents talk to their children and youth about race is *The ABCs of Survival* created by the National Black Child Development Institute (2021).

Clearly, much still needs to be done to reduce racism and improve the lives of ethnic minority individuals and groups. In the words of twentieth-century Indian philosopher and spiritual leader Mahatma Gandhi, "Our ability to reach unity in diversity will be the beauty and the test of our civilization."

Ethnicity and Aging The older adult population in the United States is becoming more ethnically diverse. Between 2018 and 2060, the percentage of the population who are from ethnic minority backgrounds is predicted to grow from 23 percent to 45 percent (U.S. Census Bureau, 2019). Despite the dramatic increase in ethnic diversity projected for older adults, the more rapidly increasing ethnic population of children and adolescents will create a diversity gap between generations.

Of special concern are ethnic minority older adults, especially African Americans and Latinxs, who are overrepresented in poverty statistics (U.S. Census Bureau, 2019). The poverty rates for African American and Latinx older adults have declined since 1975 but remain far too high (Congressional Research Service, 2019). For example, in 2017, the poverty rate for African American women age 65 and older was 21.5 percent and for African American men 16.1 percent (compared with 8.0 percent for 65-and-older non-Latinx White women and 5.8 percent for 65-and-older non-Latinx White men).

Thus, comparative information about African Americans, Latinxs, and non-Latinx Whites indicates a possible double jeopardy for elderly ethnic minority individuals who face problems related to both ageism and racism (Allen, 2016). They are likely to have a history of less education, longer periods of unemployment, worse housing conditions, poorer health, higher levels of stress, and shorter life expectancies than their non-Latinx White counterparts (Lin &

connecting with careers

Norma Thomas, Social Work Professor and Administrator

Dr. Norma Thomas has worked for more than three decades in the field of aging. She obtained her undergraduate degree in social work from Pennsylvania State University and her doctoral degree in social work from the University of Pennsylvania. Dr. Thomas' activities are varied. Early in her career, she provided social services to older adults of color in an effort to improve their lives. She currently is a professor and academic administrator at Widener University in Chester, Pennsylvania, a fellow of the Institute of Aging at the University of Pennsylvania, and the chief executive officer and cofounder of the Center on Ethnic and Minority Aging (CEMA). CEMA was formed to provide research, consultation, training, and services to benefit aging individuals of color, their families, and their communities. Dr. Thomas has organized numerous community service events that benefit older adults of color, especially African Americans and Latinxs. She has also served as a consultant to various national, regional, and state agencies in her effort to improve the lives of aging adults of color.

Dr. Norma Thomas.
Courtesy of Dr. Norma Thomas

Kelley-Moore, 2017). Also, non-Latinx White men and women with 16 years or more of schooling have a life expectancy that is 14 years higher than that of African Americans with fewer than 12 years of education (Antonucci & others, 2016).

Despite the stress and discrimination older ethnic minority individuals face, many of these older adults have developed coping mechanisms that have allowed them to survive in the dominant non-Latinx White world. Extended family networks help older minority-group individuals cope with having only the bare essentials of living and give them a sense of being loved (Antonucci & Webster, 2019). Churches in African American and Latinx communities provide avenues for meaningful social participation, feelings of power, and a sense of internal satisfaction (Hill & others, 2006). And residential concentrations of ethnic minority groups give their older members a sense of belonging. Thus, it is important to consider individual variations in the lives of aging minorities. To read about one individual who is providing help for aging minorities, see the *Connecting with Careers* profile.

Review *Connect* Reflect

LG5 Evaluate sociocultural influences on development.

Review

- How can culture, cross-cultural comparisons, and individualism/collectivism be defined? What are some outcomes of the increase in media use? How is culture related to development?
- What is socioeconomic status? How are socioeconomic status and poverty linked to development?
- What is ethnicity? How is ethnicity involved in development? What aspects of ethnicity are important to recognize?

Connect

- Compare what you learned in this section about the digitally mediated world of children and adolescents with the chapter's earlier discussion of the importance of play. What are your conclusions?

Reflect *Your Own Personal Journey of Life*

- No matter how well-intentioned people are, their life circumstances likely have given them some prejudices. If they don't have prejudices toward people with different cultural and ethnic backgrounds, other kinds of people may bring out prejudices in them. For example, prejudices can be developed about people who have certain religious or political convictions, people who are unattractive or too attractive, people with a disability, and people who live in a nearby town. As a parent or teacher, how would you attempt to reduce children's prejudices?

reach your **learning goals**

Peers and the Sociocultural World

1 Peer Relations in Childhood and Adolescence

LG1 Discuss peer relations in childhood and adolescence.

Exploring Peer Relations

- Peers are individuals who share the same age or maturity level. Peers provide a means of social comparison and a source of information about the world outside the family.
- Good peer relations may be necessary for normal social development. The inability to "plug in" to a social network is associated with a number of problems. Peer relations can be both positive and negative. Piaget and Sullivan stressed that peer relations provide the context for learning the reciprocal aspects of relationships.
- Healthy family relations usually promote healthy peer relations. Parents can model or coach their children in ways of relating to peers. Parents' choices of neighborhoods, churches, schools, and their own friends influence the pool from which their children might select possible friends. Rough-and-tumble play occurs mainly in peer relations rather than in parent-child relations. In times of stress, children usually turn to parents rather than peers. Peer relations have a more equal basis than parent-child relations.
- Contexts and individual differences influence peer relations. The frequency of peer interaction, both positive and negative, increases in the preschool years. Children spend even more time with peers during the elementary and secondary school years.
- Social information-processing skills and social knowledge are important dimensions of social cognition in peer relations. Emotion regulation plays an important role in determining whether a child's peer relationships are successful.

Peer Statuses

- Popular children are frequently nominated as a best friend and are rarely disliked by their peers. Average children receive an average number of both positive and negative nominations from their peers. Neglected children are infrequently nominated as a best friend but are not disliked by their peers. Rejected children are infrequently nominated as a best friend and are actively disliked by their peers. Controversial children are frequently nominated both as a best friend and as being disliked by peers.

Bullying

- Significant numbers of students are bullied, and bullying can result in short-term and long-term negative effects for the victim. Anxious, withdrawn children and aggressive children often are victims of bullying, and boys are far more likely to be involved in bullying than girls are.

Gender and Peer Relations

- Gender is linked to peer relations in several ways. From 4 to 12 years of age, preference for playing in same-sex groups increases. Boys' groups are larger than girls', and boys participate in more organized games than girls do. Boys are more likely to engage in rough-and-tumble play, competition, ego displays, risk taking, and dominance, whereas girls are more likely to engage in collaborative discourse. Peers play more important roles in adolescents' lives in some cultures than in others, with some cultures restricting adolescents' access to peers, especially for girls.

Adolescent Peer Relations

- Childhood groups are less formal and less heterogeneous than adolescent groups; childhood groups are also more likely to have same-sex participants. The pressure to conform to peers is strong during adolescence, especially during the eighth and ninth grades.
- Cliques and crowds assume more importance in the lives of adolescents than in the lives of children. Membership in certain crowds—especially jocks and populars—is associated with increased self-esteem. Independents also show high self-esteem.

2 Friendship

LG2 Explain the role of friendship through the life span.

Functions of Friendship

- The functions of friendship include companionship, stimulation, ego support, social comparison, and intimacy/affection.

Friendship During Childhood

- Throughout childhood and adolescence, friends are generally similar in age, sex, ethnicity, and many other factors. Although having friends is usually a developmental advantage, the quality of friendships varies and having a coercive, conflict-ridden friendship can be harmful.

Friendship During Adolescence and Emerging Adulthood

- Sullivan argued that there is a dramatic increase in the psychological importance of intimacy among close friends in adolescence. He believed friendships were important sources of support for adolescents, and research findings generally support his view.
- The friendships of adolescent girls are more intimate than those of adolescent boys. Adolescents who become friends with older individuals engage in more deviant behaviors than their counterparts with same-age friends.
- Many aspects of friendship are the same in emerging adulthood as in adolescence, although the transition to college can bring changes in friendship.

Friendship During Adulthood

- Friendships play an important role in adult development, especially in providing emotional support. Female, male, and female-male friendships often have different characteristics. Regardless of age, friendship is an important aspect of relationships. In old age, there often is more change in male than in female friendships.

3 Play and Leisure

LG3 Describe the developmental aspects of play and leisure.

Childhood

- The functions of play include affiliation with peers, tension release, advances in cognitive development, and exploration. The contemporary perspective emphasizes both social and cognitive aspects of play. The most widely studied types of play include sensorimotor and practice play, pretense/symbolic play, social play, constructive play, and games.

Adolescence

- Leisure refers to the pleasant times when individuals are free to pursue activities and interests of their own choosing—hobbies, sports, or reading, for example. U.S. adolescents have more discretionary time than do adolescents in other industrialized countries, but they often fill this time with unchallenging activities such as hanging out and watching television. U.S. adolescents spend more time in voluntary structured activities—such as hobbies, sports, and organizations—than do East Asian adolescents. Some scholars argue that U.S. adolescents have too much unstructured discretionary time that should be replaced with more challenging activities.

Adulthood

- As adults, we not only need to learn to work well, but we also need to learn to enjoy leisure. Midlife may be an especially important time for leisure because of expanded free time, availability of more money to many individuals, and the need to prepare psychologically for an active retirement.

4 Aging and the Social World

LG4 Summarize the social aspects of aging.

Social Theories of Aging

- Disengagement theory, in which older adults supposedly benefit from gradually withdrawing from society, has not held up, but socioemotional selectivity theory and activity theory are viable theories of aging.

Stereotyping of Older Adults

- There is extensive stereotyping of older adults, and ageism is a common occurrence.

Social Support and Social Integration

- Social support is an important aspect of helping people cope with stress. Older adults usually have less integrated social networks and engage in less social activity than their younger counterparts, although these findings may be influenced by cohort effects.

Successful Aging

- Increasingly, the positive aspects of aging are being studied. Factors that are linked with successful aging include an active lifestyle, positive coping skills, good social relationships and support, and self-efficacy.

5 Sociocultural Influences

LG5 Evaluate sociocultural influences on development.

Culture

- Culture refers to the behavior, patterns, beliefs, and all other products of a group of people that are passed on from generation to generation. Cross-cultural comparisons involve the comparison of one culture with one or more other cultures to gain information about the degree to which aspects are universal or culture-specific. One way that the influence of culture has been studied is to characterize cultures as individualistic (giving priority to personal rather than group goals) or collectivistic (emphasizing values that serve the group).
- There is substantial concern about the extensive increase in media/screen time among U.S. children and adolescents. Many experts argue that exposure to television violence is linked to increased aggression. Heavy TV watching is linked to lower school achievement. Children and youth also spend substantial amounts of time on the Internet, and large numbers of adolescents and college students engage in social networking. Although older adults are less likely to have a computer and to use the Internet than younger adults, they are the fastest-growing age segment of Internet users.
- Respect for the aged may vary across cultures. Factors that predict high status for older adults across cultures range from the perception that they have valuable knowledge to the belief that they serve useful functions.

Socioeconomic Status and Poverty

- Socioeconomic status (SES) is the grouping of people with similar occupational, educational, and economic characteristics. The neighborhoods and families of children have SES characteristics that are related to children's development.
- Parents from low-SES families are more concerned that their children conform to society's expectations, have an authoritarian parenting style, use physical punishment more in disciplining their children, and are more directive and less conversational with their children than higher-SES parents.
- Poverty is defined by economic hardship. The subculture of the poor is often characterized not only by economic hardship but also by social and psychological difficulties. Persistent, long-lasting poverty especially has adverse effects on children's development. Older adults who live in poverty are a special concern.

Ethnicity

- Ethnicity is based on cultural heritage, nationality characteristics, race, religion, and language. Immigration brings a number of challenges as people adapt to their new culture. Although not all ethnic minority families are poor, poverty contributes to the stress of many ethnic minority families and between ethnic minority groups and the non-Latinx White majority. African American and Latinx children are more likely than non-Latinx White children to live in single-parent families, to have larger families, and to maintain extended family connections. Racism and discrimination have been historically present in the United States, and the experiences of minority groups continue to differ from those of the majority. A special concern involves ethnicity and aging.

SCHOOLS, ACHIEVEMENT, AND WORK

chapter **outline**

1 Schools

Learning Goal 1 Describe the role of schools in development.

Contemporary Approaches to Student Learning and Assessment
Schools and Developmental Status
Educating Children with Disabilities
Socioeconomic Status and Ethnicity in Schools
Schools and the Coronavirus Pandemic

2 Achievement

Learning Goal 2 Explain the key aspects of achievement.

Extrinsic and Intrinsic Motivation
Mastery Motivation and Mindset
Self-Efficacy
Goal Setting, Planning, and Self-Monitoring
Grit
Ethnicity and Culture

3 Careers, Work, and Retirement

Learning Goal 3 Discuss career development, work, and retirement.

Career Development
Work
Retirement

preview

This chapter is about becoming educated, achieving, and working. We will begin by exploring the importance of schools in development and then examine many aspects of a topic that is closely linked to success in school and life—achievement. The final section of the chapter focuses on key aspects of career development, the role of work across the life span, and retirement as a help or a hindrance to our development.

1 Schools

LG1 Describe the role of schools in development.

- Contemporary Approaches to Student Learning and Assessment
- Schools and Developmental Status
- Educating Children with Disabilities
- Socioeconomic Status and Ethnicity in Schools
- Schools and the Coronavirus Pandemic

Cognitive Theory

Piaget's and Vygotsky's theories can be applied to children's education. Connect to "Cognitive Developmental Approaches."

We discuss many aspects of schools throughout this book, but especially in the chapters on cognitive processes and development. These chapters cover topics such as the applications of Piaget's and Vygotsky's theories to education, strategies for encouraging children's critical thinking in schools, applications of Gardner's and Sternberg's theories of intelligence to education, and bilingual education. Among the topics related to schools that we explore in this chapter are contemporary approaches to student learning, education for individuals at different developmental levels, educating children with disabilities, the impact of socioeconomic status and ethnicity in schools, and the impact of the coronavirus pandemic on schools.

Is this classroom more likely constructivist or direct instruction? Explain.
Elizabeth Crews

CONTEMPORARY APPROACHES TO STUDENT LEARNING AND ASSESSMENT

Because there are so many approaches to education, controversy swirls about the best way to teach children (Kauchak & Eggen, 2021). There also is considerable interest in finding the best way to hold schools and teachers accountable for whether children are learning (Popham, 2020).

Constructivist and Direct Instruction Approaches

The **constructivist approach** is learner centered, and it emphasizes the importance of individuals actively constructing their knowledge and understanding with guidance from the teacher. In the constructivist view, teachers should not attempt to simply pour information into children's minds. Rather, children should be encouraged to explore their world, discover knowledge, reflect, and think critically, with careful monitoring and meaningful guidance from the teacher (Bredekamp, 2020). Constructivists believe that for too long in American education children have been required to sit still, be passive learners, and rotely memorize irrelevant as well as relevant information (Sadker, Zittleman, & Koch, 2022). Today, constructivism may include an emphasis on collaboration—children working with each other in their efforts to know and understand (Parkay, 2020).

constructivist approach A learner-centered approach that emphasizes the individual's active, cognitive construction of knowledge and understanding with guidance from the teacher.

direct instruction approach A teacher-centered approach characterized by teacher direction and control, high expectations for students' progress, and maximum time spent on academic tasks.

By contrast, the **direct instruction approach** is structured and teacher centered. It is characterized by teacher direction and control, high teacher expectations for students' progress, maximum time spent by students on academic tasks, and efforts by the teacher to keep negative affect to a minimum. An important goal in the direct instruction approach is maximizing student learning time (Kauchak & Eggen, 2021).

Advocates of the constructivist approach argue that the direct instruction approach turns children into passive learners and does not adequately challenge them to think in critical and

creative ways (Sadker, Zittleman, & Koch, 2022). The direct instruction enthusiasts say that the constructivist approaches do not give enough attention to the content of a discipline, such as history or science. They also believe that the constructivist approaches are too relativistic and vague.

Some experts in educational psychology believe that many effective teachers use both a constructivist and a direct instruction approach rather than using either approach exclusively (Parkay, 2020). Further, some circumstances may require a constructivist approach, others a direction instruction approach. For example, experts increasingly recommend an explicit, intellectually engaging direct instruction approach when teaching students with a reading or a writing disability (Tompkins & Rodgers, 2020).

The whole art of teaching is the art of awakening the natural curiosity of young minds.

—Anatole France
French Novelist, 20th Century

Accountability Since the 1990s, the U.S. public and governments at every level have demanded increased accountability from schools. One result has been the spread of state-mandated tests to measure just what students have or have not learned (Chappuis, 2020). Many states have identified objectives for students in their state and created tests to measure whether students are meeting those objectives (Popham, 2020). This approach became national policy in 2002 when the No Child Left Behind (NCLB) legislation was signed into law.

No Child Left Behind (NCLB) Advocates of NCLB argued that statewide standardized testing will have a number of positive effects. These include improved student performance; more time teaching the subjects that are tested; high expectations for all students; identification of poorly performing schools, teachers, and administrators; and improved confidence in schools as test scores rise.

Critics argue that the NCLB legislation did more harm than good (Sadker, Zittleman, & Koch, 2022). One criticism stresses that using a single test as the sole indicator of students' progress and competence presents a very narrow view of students' skills (Bland & Gareis, 2018). This criticism is similar to the one leveled at IQ tests. To assess student progress and achievement, many psychologists and educators emphasize that a number of measures should be used, including tests, quizzes, projects, portfolios, classroom observations, and so on. Also, the tests used as part of NCLB did not measure creativity, motivation, persistence, flexible thinking, or social skills (Flitcroft & Woods, 2018). Critics point out that teachers ended up spending far too much class time "teaching to the test" by drilling students and having them memorize isolated facts at the expense of teaching that focuses on thinking skills, which students need for success in life (Back, 2020). Also, some individuals were concerned that No Child Left Behind educational policy overlooked the needs of students who were gifted because of its primary focus on raising the achievement level of students who were not doing well (Ballou & Springer, 2017).

Consider also the following aspect of NCLB: Each state was allowed to establish different criteria for what constituted passing or failing grades on tests designated for NCLB inclusion. An analysis of NCLB data indicated that almost every fourth-grade student in Mississippi knew how to read but only half of Massachusetts' students did (Birman & others, 2007). Clearly, Mississippi's standards for passing the reading test were far below those of Massachusetts. Like Mississippi, many states took the safe route by choosing a low passing score. Thus, while one of NCLB's goals was to raise standards for achievement in U.S. schools, apparently allowing states to set their own standards instead lowered achievement standards in many schools.

Most educators support high expectations and high standards of excellence for students and teachers. At issue, however, is whether the tests and procedures mandated by NCLB were the best means of achieving these high standards (Popham, 2020).

Common Core In 2009, the Common Core State Standards Initiative was endorsed by the National Governors Association in an effort to implement more rigorous state guidelines for educating students. The Common Core Standards specify what students should know and the skills they should develop at each grade level in various content areas (Common Core State Standards Initiative, 2014). A large majority of states have agreed to implement the Standards, yet the initiative has generated considerable controversy. Some critics argue that the Common Core Standards are simply a further effort by the federal government to control education and that they emphasize a "one size fits all" approach that pays little attention to individual variations in students (Cizek, 2019). Supporters say that the Standards provide much-needed detailed guidelines and important milestones for students to achieve (McMillen, Graves-Demario, & Kieliszek, 2018).

What are some criticisms of the NCLB legislation? What is the Common Core State Standards Initiative? What is the Every Student Succeeds Act?
Ocean/Comstock Images/Corbis

Every Student Succeeds Act (ESSA) The most recent initiative in U.S. education is the *Every Student Succeeds Act (ESSA)*, which was passed into law in December 2015 and was supposed to be fully implemented in the 2017–2018 school year. However, in 2021 implementation was still occurring and ESSA continues to be a work in progress. ESSA is giving states much more flexibility in implementing the law than was the case for NCLB (Burnette, 2021). The law replaces *No Child Left Behind*, in the process modifying but not completely eliminating standardized testing. ESSA retains annual testing for reading and writing success in grades 3 to 8, then once more in high school. The new law also allows states to scale back the role that tests play in holding schools accountable for student achievement. And at least one nonacademic factor—such as student engagement—must be assessed when tracking schools' success.

The new law continues to require states and districts to improve their lowest-performing schools and to ensure that they improve their work with historically underperforming students, such as English-language learners, ethnic minority students, and students with a disability. Also, states and districts are required to put in place challenging academic standards, although they can opt out of state standards involving Common Core. However, in 2020, the federal government suspended standardized testing when the vast majority of schools switched from in-person classes to online learning in an effort to protect students and staff from COVID-19.

SCHOOLS AND DEVELOPMENTAL STATUS

Let's now explore how schools work for students at different developmental levels. We will begin with early childhood education.

Early Childhood Education How do early education programs treat children, and how do the children fare? Our exploration of early childhood education focuses on variations in programs, education for children who are disadvantaged, and controversies in early childhood education.

What are some characteristics of the child-centered kindergarten?
Image100/PunchStock

child-centered kindergarten Education that involves the whole child by considering both the child's physical, cognitive, and socioemotional development and the child's needs, interests, and learning styles.

Montessori approach An educational philosophy in which children are given considerable freedom and spontaneity in choosing activities and are allowed to move from one activity to another as they desire.

Variations in Early Childhood Education There are many variations in the way young children are educated (Morrison & others, 2022). The foundation of early childhood education is the child-centered kindergarten.

Nurturing is a key aspect of the **child-centered kindergarten,** which emphasizes the education of the whole child and concern for his or her physical, cognitive, and socioemotional development (Bredekamp, 2020). Instruction is organized around children's needs, interests, and learning styles. Emphasis is placed on the process of learning, rather than what is learned. The child-centered kindergarten honors three principles: (1) each child follows a unique developmental pattern; (2) young children learn best through firsthand experiences with people and materials; and (3) play is extremely important in the child's total development. *Experimenting, exploring, discovering, trying out, restructuring, speaking,* and *listening* are frequent activities in excellent kindergarten programs. Such programs are closely attuned to the developmental status of 4- and 5-year-old children.

Montessori schools are patterned on the educational philosophy of Maria Montessori (1870–1952), an Italian physician-turned-educator who at the beginning of the twentieth century crafted a revolutionary approach to young children's education. The **Montessori approach** is a philosophy of education in which children are given considerable freedom and spontaneity in choosing activities. They are allowed to move from one activity to another as they desire. The teacher acts as a facilitator rather than a director (Burbank & others, 2020). The teacher shows the child how to perform intellectual activities, demonstrates interesting ways to explore curriculum materials, and offers help when the child requests it (Macia-Gual & Domingo-Penafiel, 2021). "By encouraging children to make decisions from an early age, Montessori programs seek to develop self-regulated problem solvers who can make choices and manage their time effectively" (Hyson, Copple, & Jones, 2006, p. 14).

The number of Montessori schools in the United States has expanded dramatically in recent years, from one school in 1959 to 355 schools in 1970 to approximately 5,000 in 2021, with estimates of Montessori schools worldwide at approximately 20,000 in 2016 (National Center for Montessori in the Public Sector, 2021). An experimental study with young children living in high-poverty urban areas found that over a 3-year time period those randomly assigned to Montessori programs fared better on academic achievement, social understanding, and mastery orientation than those who attended other schools (Lillard & others, 2017). And a recent study revealed that young children who attended Montessori schools displayed greater creativity than their counterparts in traditional schools (Denervaud & others, 2019).

(*Left*) Larry Page and Sergey Brin, founders of the highly successful Internet search engine Google, said that their early years at Montessori schools were a major factor in their success (International Montessori Council, 2006). During an interview with Barbara Walters, they said they learned how to be self-directed and self-starters at Montessori (ABC News, 2005). They commented that Montessori experiences encouraged them to think for themselves and allowed them the freedom to develop their own interests. (*Right*) Another leading American business executive, Jeff Bezos, became the world's richest person in 2018 and provided $2 billion to fund a new network of preschools in underserved communities that he said would be Montessori inspired (Guernsey, 2019).
(*Left*) James Leynse/Corbis/Getty Images; (*right*) Leigh Vogel/Getty Images

Some developmental psychologists favor the Montessori approach, but others believe that it neglects children's socioemotional development. For example, although the Montessori approach fosters independence and the development of cognitive skills, it deemphasizes verbal interaction between the teacher and child and between peers. Many educators and psychologists conclude that preschoolers and young elementary school children learn best through active, hands-on teaching methods such as games and dramatic play. They point out that children develop at varying rates and that schools need to allow for these individual differences (Morrison & others, 2022). They also argue that schools should focus on supporting children's socioemotional development as well as their cognitive development. Educators refer to this type of schooling as **developmentally appropriate practice (DAP),** which is based on knowledge of the typical development of children within a particular age span (age appropriateness), as well as on the uniqueness of the individual child (individual appropriateness). DAP emphasizes the importance of creating settings that reflect children's interests and capabilities while encouraging them to be active learners (Bredekamp, 2020). Desired outcomes for DAP include thinking critically, working cooperatively, solving problems, developing self-regulatory skills, and enjoying learning. The emphasis in DAP is on the process of learning rather than on its content.

What are some important aspects of developmentally appropriate practice?
Ariel Skelley/Blend Images/Getty Images

Education for Young Children Who Are Disadvantaged For many years, U.S. children from low-income families did not receive any education before they entered the first grade. Often when they began first grade they were already several steps behind their classmates in readiness to learn. In the summer of 1965, the federal government initiated **Project Head Start** in an effort to break the cycle of poverty and substandard education for young children. Head Start is a compensatory program designed to give children from low-income families the opportunity to acquire skills and experiences that are important for success in school. More than half a century after the program was founded, Head Start continues to be the largest federally funded program for U.S. children, with almost 1 million children enrolled in it annually.

Head Start programs are not all created equal, and more attention needs to be given to developing consistently high-quality Head Start programs (Slater & others, 2021; Sommer & others, 2020). In one such recent effort, a social-emotional learning program and a coordinated interactive reading program were used to enrich Head Start classrooms, an intervention that

developmentally appropriate practice Education that focuses on the typical developmental patterns of children (age appropriateness) as well as on the uniqueness of each child (individual appropriateness).

Project Head Start Compensatory prekindergarten education designed to provide children from low-income families the opportunity to acquire skills and experiences important for school success.

connecting with careers

Yolanda Garcia, Director of Children's Services, Head Start

Yolanda Garcia has been the director of the Children's Services Department of the Santa Clara, California, County Office of Education since 1980. As director, she is responsible for managing child development programs for 2,500 3- to 5-year-old children in 127 classrooms. Her training includes two master's degrees: one in public policy and child welfare from the University of Chicago and another in educational administration from San Jose State University.

Garcia has served on many national advisory committees that have resulted in improvements in the staffing of Head Start programs. Most notably, she served on the Head Start Quality Committee that recommended the development of Early Head Start and revised performance standards for Head Start programs. Garcia currently is a member of the American Academy of Sciences Committee on the Integration of Science and Early Childhood Education.

Yolanda Garcia, Director of Children's Services/Head Start, works with a Head Start child in Santa Clara, California.

resulted is the children having significantly lower rates of conduct problems and negative emotional symptoms, as well as better peer relations, in adolescence (Bierman & others, 2021). One person who is strongly motivated to make Head Start a valuable learning experience for young children from disadvantaged backgrounds is Yolanda Garcia. To read about her work, see the *Connecting with Careers* profile.

Mixed results have been found for Head Start (Lee, 2019). One study found that one year of Head Start was linked to higher performance in early math, early reading, and receptive vocabulary (Miller & others, 2014). Also, in a recent study of 3- to 4-, 5- to 6-, and 8- to 9-year-olds, foster children who participated in Head Start programs had better cognitive, socioemotional, and health outcomes than foster children who did not participate in Head Start programs, with the outcomes strongest in 8- to 9-year-olds (Lee, 2020). Nonetheless, too often early gains occur through Head Start and then evaporate during elementary school (Jenkins & others, 2018).

Controversy Over Curriculum A current controversy in early childhood education involves what the curriculum for early childhood education should be (Morrison & others, 2022). On one side are those who advocate a child-centered, constructivist approach much like that emphasized by the National Association for the Education of Young Children (NAEYC), along the lines of developmentally appropriate practice. On the other side are those who advocate an academic, direct-instruction approach.

What is the curriculum controversy in early childhood education?
Ronnie Kaufman/Corbis/Getty Images

In practice, many high-quality early childhood education programs encompass both academic and constructivist approaches. Many education experts such as Lilian Katz (1999), however, worry about academic approaches that place too much pressure on young children to achieve and don't provide opportunities to actively construct knowledge. Competent early childhood programs should focus on both cognitive development and socioemotional development, not exclusively on cognitive development (Bredekamp, 2020).

Elementary School For many children, entering the first grade signals a change from being a "home-child" to being a "school-child"—a situation in which they experience new roles and obligations (Gonzalez-Moreira, Ferreira, & Vidal, 2021). Children take up the new role of being a student, interact, develop new relationships, adopt new reference groups, and develop new standards by which to judge themselves (Collins & Madsen, 2019). School provides children with a rich source of new ideas to shape their sense of self.

Too often, however, early schooling proceeds mainly on the basis of negative feedback. For example, children's self-esteem in the later years of elementary school is lower than it is in the earlier years, and older children rate themselves as less smart, less good, and less hardworking than do younger ones (Eccles, 2003).

The transition from elementary to middle or junior high school occurs at the same time as a number of other developmental changes. *What are some of these other developmental changes?*
Creatas Images/Punchstock/Getty Images

Educating Adolescents How do students experience the transition from elementary to middle or junior high school? What are the characteristics of effective schools for adolescents?

The Transition to Middle or Junior High School The transition to middle school or junior high school can be stressful. Why? The transition takes place at a time when many changes—in the individual, in the family, and in school—are occurring simultaneously (Crosnoe & Ressler, 2019). These changes include puberty and related concerns about body image; the emergence of at least some aspects of formal operational thought, including accompanying changes in social cognition; increased responsibility and decreased dependency on parents; change to a larger, more impersonal school structure; change from one teacher to many teachers and from a small, homogeneous set of peers to a larger, more heterogeneous set of peers; and an increased focus on achievement and performance and their assessment. Also, when students make the transition to middle or junior high school, they experience the **top-dog phenomenon,** moving from being the oldest, biggest, and most powerful students in elementary school to being the youngest, smallest, and least powerful students in middle or junior high school. A recent study in Spain found that middle school students had a lower level of self-concept in a number of areas (academic, social, family, and physical) than elementary school students did (Onetti, Fernandez-Garcia, & Castillo-Rodriguez, 2019). Also, a recent study revealed that compared with students in elementary school, students in the first year of middle school had lower levels of adaptive coping and higher levels of maladaptive coping (Skinner & Saxton, 2020).

The transition to middle or junior high school may also have positive aspects. Students are more likely to feel grown up, have more subjects from which to select, have more opportunities to spend time with peers and locate compatible friends, and enjoy increased independence from direct parental monitoring. They also may be more challenged intellectually by academic work.

Effective Schools for Young Adolescents Educators and psychologists worry that junior high and middle schools have become watered-down versions of high schools, mimicking their curricular and extracurricular schedules. Critics argue that these schools should offer activities that reflect a wide range of individual differences in biological and psychological development among young adolescents (Powell, 2020). The Carnegie Foundation (1989) issued an extremely negative evaluation of U.S. middle schools. It concluded that most young adolescents attended massive, impersonal schools, learned from irrelevant curricula, trusted few adults in school, and lacked access to health care and counseling. It recommended that the nation develop smaller "communities" or "houses" to lessen the impersonal nature of large middle schools; have lower student-to-counselor ratios (10 to 1 instead of several hundred to 1); involve parents and community leaders in schools; develop new curricula; have teachers team teach in more flexibly designed curriculum blocks that integrate several disciplines; boost students' health and fitness with more in-school physical education programs; and help students who need public health care to get it. Three decades later, many of the Carnegie Foundation's recommendations have not been implemented, and middle schools throughout the nation continue to need a major redesign if they are to be effective in educating adolescents (Voight & Hanson, 2017).

High School Just as there are concerns about U.S. middle school education, so are there concerns about U.S. high school education (Price & Corrin, 2020). A recent analysis indicated that only 25 percent of U.S. high school graduates have the academic skills required for success in college (Bill & Melinda Gates Foundation, 2017). Not only are many high school graduates poorly prepared for college, they also are poorly prepared for the demands of the modern, high-performance digital workplace (Bill & Melinda Gates Foundation, 2020).

Critics stress that many high schools foster passivity and that schools should create a variety of pathways for students to achieve an identity. Many students graduate from high school

top-dog phenomenon The circumstance of moving from the top position in elementary school to the youngest, smallest, and least powerful position in middle or junior high school.

with inadequate reading, writing, and mathematical skills; of these, many go on to college and must enroll in remediation classes there. Other students drop out of high school and do not have skills that would allow them to obtain decent jobs, much less to be informed citizens.

The transition to high school can have problems, just as the transition to middle school can (Epstein & others, 2021). These problems may include the following (Roder & Muller, 2020): high schools are often even larger, more bureaucratic, and more impersonal than middle schools are; there isn't much opportunity for students and teachers to get to know each other, which can lead to distrust; and teachers too infrequently make content relevant to students' interests. Such experiences likely undermine the motivation of students. In a recent study, increased teacher-student conflict during the transitions from elementary to middle school and from middle to high school were linked to an increase in externalizing symptoms (fighting with others, for example) in the first year at the new school (Longobardi & others, 2019).

Robert Crosnoe's (2011) book, *Fitting In, Standing Out,* highlighted another major problem with U.S. high schools—how the negative social aspects of adolescents' lives can undermine their academic achievement. In his view, adolescents become immersed in complex peer group cultures that demand conformity. High school is supposed to be about getting an education, but in reality for many youth it is as much about navigating the social worlds of peer relations that may or may not value education and academic achievement. Adolescents who are different may fail to fit in, such as those who are obese or gay, and become stigmatized. Crosnoe recommends increased school counseling services, expanded extracurricular activities, and improved parental monitoring to reduce such problems (Crosnoe, Pivnick, & Benner, 2019).

Adolescents in U.S. schools usually have opportunities to participate in a wide array of extracurricular activities beyond their academic courses. These opportunities include such diverse activities as sports, academic clubs, band, drama, and math clubs. Researchers have found that participation in extracurricular activities is linked to higher grades, greater school engagement and motivation, less likelihood of dropping out of school, improved probability of going to college, higher self-esteem, and lower rates of depression, delinquency, and substance abuse (Denault & Guay, 2017). Also, adolescents benefit from engaging in a variety of extracurricular activities more than from focusing on a single extracurricular activity. In a longitudinal study, both breadth and intensity of involvement in extracurricular activities in the tenth grade were associated with higher educational attainment 8 years after high school (Haghighat & Knifsend, 2019).

Yet another concern about U.S. high schools involves students dropping out of school (Bill & Melinda Gates Foundation, 2020). In the first two decades of the twenty-first century, U.S. high school dropout rates declined (National Center for Education Statistics, 2020). In the 1940s, more than half of U.S. 16- to 24-year-olds had dropped out of school; by 1990, this rate had dropped to 12 percent, and by 2000 it was 10.9 percent. In 2018, the dropout rate had decreased further to 5.3 percent. The lowest dropout rate in 2017 occurred for Asian American adolescents (1.9 percent), followed by non-Latinx White adolescents (4.2 percent), African American adolescents (6.4 percent), and Latinx adolescents (8 percent) (National Center for Education Statistics, 2020). The dropout rates have dropped considerably since 2000 when the dropout rate for non-Latinx Whites was 6.9, for African Americans 13.1 percent, and for Latinxs 27.8 percent.

An important educational goal is to increase the high school graduation rate of Native youth. An excellent strategy to accomplish this goal is high-quality early childhood educational programs such as this one at St. Bonaventure Indian School on the Navajo Nation in Thoreau, New Mexico.
Jim West/Alamy Stock Photo

Gender differences have characterized U.S. dropout rates for many decades, but they have been narrowing in recent years. In 2017, the dropout rate for males was 6.2 percent and for females it was 4.4 percent, compared with 12.0 and 9.9 respectively in 2000 (National Center for Education Statistics, 2020).

The average U.S. high school dropout rates just described mask some very high dropout rates in low-income areas of inner cities. For example, in high-poverty areas of some cities such as Detroit, Cleveland, and Chicago, dropout rates can reach 50 percent or higher. "I Have a Dream" (IHAD) is an innovative, comprehensive, long-term dropout prevention program administered by the National "I Have a Dream" Foundation in New York. Since the National IHAD Foundation was established in 1986, it has grown to comprise more than 180 projects in 64 cities and 27 states serving more than 15,000 children ("I Have a Dream" Foundation, 2020). Local IHAD projects around the country "adopt" entire grades (usually the third or fourth) from public elementary schools, or corresponding age cohorts from public housing

These adolescents are participating in the "I Have a Dream" (IHAD) Program, a comprehensive, long-term dropout prevention program that has been very successful. *What are some other strategies for reducing high school dropout rates?*
Courtesy of "I Have a Dream" Foundation of Boulder County

developments. These children—"Dreamers"—are then provided with a program of academic, social, cultural, and recreational activities throughout their elementary, middle school, and high school years. When participants complete high school, IHAD provides the tuition assistance necessary for them to attend a state or local college or vocational school. Evaluations of IHAD programs have found dramatic improvements in grades, test scores, and school attendance, as well as reduced rates of behavioral problems of Dreamers.

College and Adult Education Having a college degree is a strong asset. College graduates can enter careers that will earn them considerably more money in their lifetimes than those who do not go to college, and income differences between college graduates and high school graduates continue to grow (*Occupational Outlook Handbook, 2020-2021*). Individuals with a college education also live two years longer on average than their counterparts who only graduate from high school.

Transition to College What is the transition to college like? Are adults seeking more education than in the past? Just as the transition from elementary school to middle or junior high school involves change and possible stress, so does the transition from high school to college (Linkow & others, 2021). The two transitions have many parallels. Going from being a senior in high school to being a freshman in college replays the top-dog phenomenon of transferring from the oldest and most powerful group of students to the youngest and least powerful group of students that occurred earlier as adolescence began. For many students, the transition from high school to college involves movement to a larger, more impersonal school structure; interaction with peers from more diverse geographical and sometimes more diverse ethnic backgrounds; and increased focus on achievement and its assessment. Further, for many students, the transition to college includes new living arrangements and new social circles as well (LaBelle, 2020). And like the transition from elementary to middle or junior high school, the transition from high school to college can involve positive features. Students are more likely to feel grown up, have more subjects from which to select, have more time to spend with peers, have more opportunities to explore different lifestyles and values, enjoy greater independence from parental monitoring, and be challenged intellectually by academic work (Santrock & Halonen, 2013).

The transition from high school to college often involves positive as well as negative features. In college, students are likely to feel grown up, be able to spend more time with peers, have more opportunities to explore different lifestyles and values, and enjoy greater freedom from parental monitoring. However, college involves a larger, more impersonal school structure and an increased focus on achievement and its assessment. *What was your transition to college like?*
Stockbyte/Stockdisc/Getty Images

Today's college students experience more stress and are more depressed than those of the past, according to a national study of more than 300,000 freshmen at more than 500 colleges and universities (Stolzenberg & others, 2020). In 2019, 42.7 percent (up from 16 percent in 1985 and 27 percent in 2009) said they frequently "felt overwhelmed with what I have to do." In 2017, female students (55 percent) were almost twice as likely as their male counterparts (28 percent) to say that they felt overwhelmed with all they had to do. And college freshmen in 2019 indicated that they felt more depressed than their counterparts from the 1980s had indicated. The pressure to succeed in college, get a great job, and make lots of money were pervasive concerns of these students.

What makes college students happy? One study of 222 undergraduates compared the upper 10 percent of college students who were very happy with average and very unhappy college students (Diener & Seligman, 2002). The very happy college students were highly social, more extraverted, and had stronger romantic and social relationships than the less happy college students, who spent more time alone (see Figure 1).

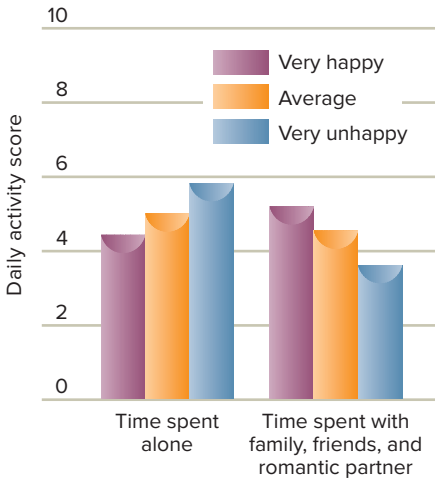

FIGURE 1

DAILY ACTIVITY SELF-RATINGS AND COLLEGE STUDENTS' HAPPINESS. In this study of undergraduates, the daily activity scores reflect mean times with 0 representing no time and 8 indicating 8 hours per day (Diener & Seligman, 2002). Students were classified as very happy, average, or very unhappy based on their self-ratings.

Many immigrants to the United States, such as this Spanish-speaking woman enrolled in an English class, take adult education classes. *What are some trends in adult education?*
Newscom

Adult Education An increasing number of adults older than the traditional college age go to school. Adult education refers to all forms of schooling and learning in which adults participate. Adult education includes literacy training, community development, university credit programs, on-the-job training, and continuing professional education. Institutions that offer education to adults include colleges, libraries, museums, government agencies, businesses, and churches.

In 1985, individuals over the age of 25 represented 45 percent of the enrollment in credit courses in the United States. In the third decade of the twenty-first century, that figure is over 50 percent. A large and expanding number of college students are adults who pursue education and advanced degrees on a part-time basis. The increase in adult education is a result of increased leisure time for some individuals and the need to update information and skills for others. Some older adults simply take educational courses because they enjoy learning and want to keep their minds active.

Women represent the majority of adult learners—almost 60 percent. In the 35-and-over age group, women constitute an even greater percentage of the enrollment in adult education—almost 70 percent. Some of these women devoted their early adult lives to parenting and decided to go back to school to prepare for a new career.

Going back to a classroom after being away from school for a long time can be stressful. However, returning students bring a wealth of experience to college and should feel good about the contributions they can make.

Disability	Percentage of All Students Served Under the Individuals with Disabilities Act
Learning disabilities	33
Speech and language impairments	19
Other Health Impairments	17
Autism	11

Intellectual disability	6
Emotional disturbance	5

FIGURE **2**

U.S. CHILDREN WITH A DISABILITY WHO RECEIVE SPECIAL EDUCATION SERVICES. Figures are for the 2018–2019 school year and represent the seven categories with the highest numbers and percentages of children. Both learning disability and attention deficit hyperactivity disorder are combined in the learning disabilities category (National Center for Education Statistics, 2020).

EDUCATING CHILDREN WITH DISABILITIES

So far we have discussed schools as they are experienced by the majority of U.S. students. Of all children in the United States, 14 percent from 3 to 21 years of age received special education or related services in 2018–2019, an increase of 3 percent since 1980–1981 (National Center for Education Statistics, 2020). Figure 2 shows the seven largest groups of students with a disability who were served by federal programs during the 2018–2019 school year (National Center for Education Statistics, 2020). As indicated in Figure 2, students with a learning disability were by far the largest group of students with a disability to receive special education, followed by children with speech or language impairments, intellectual disability, and emotional disturbance. Note that the U.S. Department of Education includes both students with a learning disability and students with ADHD in the category of learning disability.

Learning Disabilities The U.S. government defines whether a child should be classified as having a learning disability in the following way: A child with a **learning disability** has difficulty in learning that involves understanding or using spoken or written language, and the difficulty can appear in listening, thinking, reading, writing, and spelling (Turnbull & others, 2020). A learning disability also may involve difficulty in doing mathematics. To be classified as a learning disability, the learning problem is not primarily the result of visual, hearing, or motor disabilities; intellectual disability; emotional disorders; or due to environmental, cultural, or economic disadvantage.

About three times as many boys as girls are classified as having a learning disability. Among the explanations for this gender difference are a greater biological vulnerability among boys and *referral bias.* That is, boys are more likely than girls to be referred by teachers for treatment because of troublesome behavior.

Also, recent research conducted by the Centers for Disease Control found that in 2018 for 3- to 17-year-olds, 16.9 percent of African American children and adolescents were reported as ever having a learning disability or attention deficit hyperactivity disorder (ADHD) compared with 14.7 percent of non-Latinx Whites and 11.9 percent of Latinxs (Zablotsky & Alford, 2020).

Socioeconomic variations also are linked to learning disabilities, with African American and Latinx students being disproportionately identified (Shifrer, Muller, & Callahan, 2011). However, much of the variation in ethnic differences is largely accounted for by the lower overall SES status of children of color.

Approximately 80 percent of children with a learning disability have a reading problem (Shaywitz, Gruen, & Shaywitz, 2007). Three types of learning disabilities are dyslexia, dysgraphia, and dyscalculia:

- **Dyslexia** is a category reserved for individuals with a severe impairment in their ability to read and spell (Remien & Marwaha, 2021).
- **Dysgraphia** is a learning disability that involves difficulty in handwriting (Cabrero & De Jesus, 2021). Children with dysgraphia may write very slowly, their writing products may be virtually illegible, and they may make numerous spelling errors because of their inability to match up sounds and letters.
- **Dyscalculia,** also known as developmental arithmetic disorder, is a learning disability that involves difficulty in math computation (Cardenas & others, 2021).

The precise causes of learning disabilities have not yet been determined (Daucourt & others, 2020). To reveal any regions of the brain that might be involved in learning disabilities, researchers use brain-imaging techniques such as magnetic resonance imaging (Li & others, 2020) (see Figure 3). This research indicates that it is unlikely that learning disabilities reside in a single, specific brain location. More likely, learning disabilities involve problems integrating information from multiple brain regions or subtle difficulties in brain structures and functions (Banker & others, 2020; Kim, 2021).

FIGURE **3**

BRAIN SCANS AND LEARNING DISABILITIES. An increasing number of studies are using MRI brain scans to examine the brain pathways involved in learning disabilities. Shown here is 9-year-old Patrick Price, who has dyslexia. Patrick is going through an MRI scanner disguised by drapes to look like a child-friendly castle. Inside the scanner, children must lie virtually motionless as words and symbols flash on a screen, and they are asked to identify them by clicking different buttons. Manuel Balce Ceneta/AP Images

Interventions with children who have a learning disability often focus on improving reading ability (Gunning, 2020). Intensive instruction in reading over a period of time by a competent teacher can help many children (Dewitz & others, 2020).

Attention Deficit Hyperactivity Disorder (ADHD)

Attention deficit hyperactivity disorder (ADHD) is a disability in which children consistently show one or more of the following characteristics over a period of time: (1) inattention, (2) hyperactivity, and (3) impulsivity. Children who are inattentive have so much difficulty focusing on any one thing that they may get bored with a task after only a few minutes—or even seconds. Children who are hyperactive show high levels of physical activity, seeming to be almost constantly in motion. Children who are impulsive have difficulty curbing their reactions; they do not do a good job of thinking before they act. Depending on the characteristics that children with ADHD display, their diagnosis may be (1) ADHD with predominantly inattention, (2) ADHD with predominantly hyperactivity/impulsivity, or (3) ADHD with both inattention and hyperactivity/impulsivity.

The number of children diagnosed and treated for ADHD has increased substantially in recent decades. The Centers for Disease Control and Prevention (2016) estimates that ADHD has continued to increase in 4- to 17-year-old children, going from 8 percent in 2003 to 9.5 percent in 2007 and 11 percent in 2016. According to the Centers for Disease Control and Prevention, 13.2 percent of U.S. boys and 5.6 percent of U.S. girls have ever been diagnosed with ADHD. The disorder is diagnosed four to nine times as often in boys as in girls. There is controversy, however, about the increased diagnosis of ADHD (Hallahan, Kauffman, & Pullen, 2019). Some experts attribute the increase mainly to heightened awareness of the disorder, while others believe that many children are being incorrectly diagnosed.

While earlier studies have found that an ADHD diagnosis was more likely in non-Latinx White children than children of color (Miller, Nigg, & Miller, 2009), as indicated in the coverage of learning disabilities, the Centers for Disease Control and Prevention (Zablotsky & Alford, 2020) recently found that 3- to 17-year-old African Americans (16.9 percent) were more likely to be diagnosed with ADHD or a learning disability than non-Latinx Whites (14.7 percent) or Latinxs (11.9 percent). However, some evidence suggests that African American and Latinx children and adolescents are actually under-diagnosed with ADHD and over-diagnosed with a disruptive behavior disorder in comparison with non-Latinx White children, leading some researchers to question whether unconscious bias is influencing diagnosis of ADHD (Fadus & others, 2020).

learning disabilities Disabilities in which children experience difficulty in learning that involves understanding or using spoken or written language; the difficulty can appear in listening, thinking, reading, writing, and spelling. A learning disability also may involve difficulty in doing mathematics. To be classified as a learning disability, the learning problem is not primarily the result of visual, hearing, or motor disabilities; intellectual disability; emotional disorders; or environmental, cultural, or economic disadvantage.

dyslexia A learning disability that involves a severe impairment in the ability to read and spell.

dysgraphia A learning disability that involves difficulty in handwriting.

dyscalculia Also known as developmental arithmetic disorder, this term refers to a learning disability that involves difficulty in math computation.

attention deficit hyperactivity disorder (ADHD) A disability in which children consistently show one or more of the following characteristics: (1) inattention, (2) hyperactivity, and (3) impulsivity.

Many children with ADHD show impulsive behavior, such as this boy reaching to pull a girl's hair. *How would you handle this situation if you were a teacher and this happened in your classroom?*
Nicole Hill/Rubberball/Getty Images

Definitive causes of ADHD have not been found (Mash & Wolfe, 2019). However, a number of causes have been proposed (Magnus & others, 2021). Some children likely inherit a tendency to develop ADHD from their parents (Henriquez-Henriquez & others, 2020). Other children likely develop ADHD because of damage to their brain during prenatal or postnatal development (Debnath & others, 2021). Among early possible contributors to ADHD are maternal exposure to cigarettes and alcohol during pregnancy (Biederman & others, 2020), a high level of maternal stress during prenatal development (Manzari & others, 2019), and low birth weight and preterm birth (Walczak-Kozlowska & others, 2020). Further, recent research indicated that low socioeconomic status was associated with a higher risk for developing ADHD and this low SES was linked to less effective brain functioning (Machlin, McLaughlin, & Sheridan, 2020).

As with learning disabilities, the development of brain-imaging techniques is leading to a better understanding of ADHD (Zou & Yang, 2021). One study revealed that peak thickness of the cerebral cortex occurred three years later (10.5 years) in children with ADHD than in children without ADHD (peak at 7.5 years) (Shaw & others, 2007). The delay was more prominent in the prefrontal regions of the brain that are especially important in attention and planning (see Figure 4). Another study found delayed development in the brain's frontal lobes among children with ADHD, which likely was due to delayed or decreased myelination (Nagel & others, 2011). Researchers also are exploring the roles that various neurotransmitters, such as serotonin (Nilsen & Tulve, 2020), dopamine (Cai & others, 2021), and GABA (Puts & others, 2020), might play in ADHD.

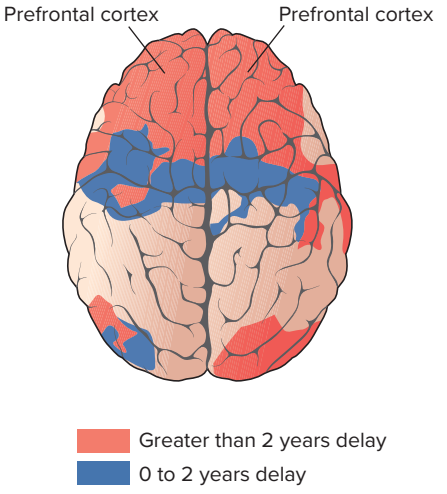

FIGURE **4**

REGIONS OF THE BRAIN IN WHICH CHILDREN WITH ADHD HAD A DELAYED PEAK IN THE THICKNESS OF THE CEREBRAL CORTEX.

Note: The greatest delays occurred in the prefrontal cortex.

The delays in brain development just described are in areas linked to executive function (Karr & others, 2021). Recent studies of children with ADHD have focused on their difficulty doing tasks involving executive function, such as behavioral inhibition when necessary, use of working memory, and effective planning (Koffler & others, 2020). Researchers also have found deficits in theory of mind in children with ADHD (Austin, Bondu, & Elsner, 2020). Children diagnosed with ADHD have an increased risk of school dropout, disordered eating, adolescent pregnancy, substance use problems, and antisocial behavior (Obsuth & others, 2020; Tistarelli & others, 2020). Experts previously thought that most children "grow out" of ADHD. However, evidence suggests otherwise (Weibel & others, 2020). As many as 70 percent of adolescents (Sibley & others, 2012) and 66 percent of adults (Buitelaar, Karr, & Asherton, 2010) who were diagnosed as children continue to experience ADHD symptoms.

Stimulant medication such as Ritalin or Adderall (which has fewer side effects than Ritalin) is effective in improving the attention of many children with ADHD, but it usually does not improve their attention to the same level as children who do not have ADHD (Luo & Levin, 2017). A recent research review also concluded that stimulant medications are effective in treating ADHD during the short term but that longer-term benefits of stimulant medications are not clear (Rajeh & others, 2017). A meta-analysis concluded that behavior management treatments are effective in reducing the effects of ADHD (Fabiano & others, 2009). Researchers have often found that combining medication (such as Ritalin) with behavior management often (but not always) improves the behavior of children with ADHD better than medication alone or behavior management alone (Centers for Disease Control and Prevention, 2016).

The main form of treatment for ADHD is stimulant drugs, especially Ritalin and Adderall. There is increasing concern that children who are given stimulant drugs such as Ritalin or Adderall are at increased risk for developing substance abuse problems, although research findings so far have been mixed (van der Burg & others, 2019).

In addition to stimulant drug treatment and behavior management, recently three other strategies for treating ADHD have been explored—neurofeedback, mindfulness training, and exercise:

- *Neurofeedback.* Researchers are exploring the possibility that neurofeedback might improve the attention of children with ADHD (Dobrakowski & Lebecka, 2020). Neurofeedback trains individuals to become more aware of their physiological responses so that they can attain better control over their brain's prefrontal cortex, where executive control primarily occurs. Neurofeedback produces audiovisual profiles of brain waves so that individuals can

Cognitive Processes
Mindfulness training is being used to improve students' executive function. Connect to "Information Processing."

learn how to achieve normal EEG functioning (Lambez & others, 2020). A recent review of meta-analyses and randomized experiments concluded that neurofeedback has medium to large effects on ADHD, with 32 to 47 percent remission rates for 6 to 12 months (Arns & others, 2020). And another extensive set of meta-analyses concluded that neurofeedback significantly improves inattention symptoms in children with ADHD but that stimulant medication is more effective in doing so than neurofeedback (Riesco-Matias & others, 2021).

- *Mindfulness training.* Mindfulness training recently has been given to children, adolescents, and adults with ADHD (Siebelink & others, 2020; Zaccari & others, 2021). A recent meta-analysis concluded that mindfulness training significantly improved the attention of children with ADHD (Cairncross & Miller, 2020).
- *Exercise.* Exercise also is being investigated as a possible treatment for children with ADHD (Nejati & Derakhshan, 2021; Villa-Gonzalez & others, 2020). A recent meta-analysis concluded that regular exercise was more effective than neurofeedback, cognitive training, or cognitive therapy in improving cognitive difficulties (attention, inhibition, and working memory deficiencies, for example) in treating ADHD (Lambez & others, 2020). And in a recent study, children with ADHD were 21 percent less likely to engage in regular exercise than children not diagnosed with ADHD (Mercurio & others, 2021).

Despite the encouraging recent studies of using neurofeedback, mindfulness training, and exercise to improve the attention of children with ADHD, it still remains to be determined whether these non-drug therapies are as effective as stimulant drugs or whether they benefit children as add-ons to stimulant drugs to provide a combination treatment (Riesco-Matias & others, 2019).

developmental **connection**
Conditions, Diseases, and Disorders
Autistic children have difficulty in developing a theory of mind, especially in understanding others' beliefs and emotions. Connect to "Information Processing."

Autism Spectrum Disorders

Autism spectrum disorders (ASDs) are characterized by problems in social interaction, problems in verbal and nonverbal communication, and repetitive behaviors (Lord & others, 2020). A recent study also found that a lower level of working memory was the executive function most strongly associated with autism spectrum disorders (Ziermans & others, 2017). Further, children with these disorders may also show atypical responses to sensory experiences (National Institute of Mental Health, 2020).

Estimates of the prevalence of autism spectrum disorders tracked over time indicate that they are becoming more common or are increasingly being detected and labeled (Hall, 2018). Autism was once thought to affect only 1 in 2,500 individuals. However, in a more recent survey, the estimated proportion of 8-year-old children with autism spectrum disorders had increased to 1 in 54 (Centers for Disease Control and Prevention, 2020). Also, in 2018–2019, 11 percent of all children receiving special education in U.S. schools were autistic (compared with only 6.5 percent in 2010–2011) (National Center for Education Statistics, 2020). Further, in a recent survey, autism spectrum disorders were identified four times more often in boys than in girls (Centers for Disease Control and Prevention, 2020). Also, in two surveys, only a minority of parents reported that their child's autism spectrum disorder had been identified prior to 3 years of age, and one-third to one-half of the cases were identified after 6 years of age (Sheldrick, Maye, & Carter, 2017). However, researchers are conducting studies that seek to identify earlier determinants of autism spectrum disorder (Hudry & others, 2021). For example, a recent research summary noted that early warning signs for ASD were lack of social gestures at 12 months, using no meaningful words at 18 months, and having no interest in other children or no spontaneous two-word phrases at 24 months (Tsang & others, 2019).

What causes autism spectrum disorders? The current consensus is that autism is a brain dysfunction characterized by abnormalities in brain structure and neurotransmitters (Takumi & others, 2020). Recent interest has focused on brain networks and a lack of connectivity between brain regions as a key factor in autism (Rolls & others, 2020).

Genetic factors also are likely to play a role in the development of autism spectrum disorders (Li & others, 2020). There is no evidence that autism is caused by family dynamics.

Children with autism benefit from a well-structured classroom, individualized teaching, and small-group instruction. Behavior modification techniques are sometimes effective in helping autistic children learn (Wheeler & Richey, 2019).

What characterizes autism spectrum disorders?
Rob Crandall/Alamy Stock Photo

autism spectrum disorders (ASDs) Disorders involving problems in social interaction, verbal and nonverbal communication, and repetitive behaviors that are linked to organic brain dysfunction.

connecting with careers

Carissa Barnes, Special Education Teacher

Carissa Barnes is a lead special education resource teacher in the Montgomery County Public Schools in Maryland. She has undergraduate and master's degrees in special education from the University of Maryland–College Park. When Carissa was in middle school, she participated in service learning that involved volunteering at a child care center where too often families were turned away because they did not have enough money or their child's needs were too severe. Such experiences motivated her to pursue a career in educating children with special needs. Marissa says that every day in her work she is gratified to see students with special needs overcome their limitations and learn effectively (Office of Special Education and Rehabilitative Services Blog, 2018).

Special education teachers work with students who have a wide range of disabilities. They adapt educational content and materials in subjects such as reading, writing, and math to make them accessible to special education students. Public schools require a bachelor's degree and state-issued certification in special education; private schools require a bachelor's degree but not certification.

IDEA mandates free, appropriate education for all children. *What services does IDEA mandate for children with disabilities?*
E.D. Torial/Alamy Stock Photo

Educational Issues Until the 1970s most U.S. public schools either refused enrollment to children with disabilities or inadequately served them. This changed in 1975 when Public Law 94-142, the Education for All Handicapped Children Act, required that all students with disabilities be given a free, appropriate public education. In 1990, Public Law 94-142 was recast as the Individuals with Disabilities Education Act (IDEA). IDEA was amended in 1997 and then reauthorized in 2004 and renamed the Individuals with Disabilities Education Improvement Act.

IDEA spells out broad mandates for services to children with disabilities of all kinds (Bolourian, Tipton-Fisler, & Yassine, 2020). These services include evaluation and eligibility determination, appropriate education and an individualized education plan (IEP), and education in the least restrictive environment (LRE) (Turnbull & others, 2020).

An **individualized education plan (IEP)** is a written statement that spells out a program that is specifically tailored for a student with a disability. The **least restrictive environment (LRE)** is a setting that is as similar as possible to the one in which children who do not have a disability are educated (Ainscow, 2020). This provision of the IDEA has given a legal basis to efforts to educate children with a disability in the regular classroom. The term **inclusion** describes educating a child with special educational needs full-time in the regular classroom (Gottfried & Kirksey, 2020). Recent analysis indicated that in 2016, 63 percent of students with disabilities spent 80 percent or more of their total school time in the regular classroom—the highest level since inclusion began to be assessed (National Center for Education Statistics, 2017). To read about the career of a special education teacher, see *Connecting with Careers.*

individualized education plan (IEP) A written statement that spells out a program tailored to meet the needs of a child with a disability. The plan should be (1) related to the child's learning capacity, (2) specially constructed to meet the child's individual needs and not merely a copy of what is offered to other children, and (3) designed to provide educational benefits.

least restrictive environment (LRE) A setting that is as similar as possible to the one in which children without a disability are educated.

inclusion Education of a child with special educational needs full-time in the regular classroom.

Many legal changes regarding children with disabilities have been extremely positive (Turnbull & others, 2020). Compared with several decades ago, far more children today are receiving competent, specialized services. For many children, inclusion in the regular classroom, with modifications or supplemental services, is appropriate. However, some leading experts on special education argue that some children with disabilities may not benefit from inclusion in the regular classroom (Hallahan, Kauffman, & Pullen, 2019). James Kauffman and his colleagues, for example, advocate a more individualized approach that does not necessarily involve full inclusion but allows options such as special education outside the regular classroom with trained professionals and adapted curricula (Kauffman, McGee, & Brigham, 2004). They go on to say, "We sell students with disabilities short when we pretend that they are not different from typical students. We make the same error when we pretend that they must not be expected to put forth extra effort if they are to learn to do some things—or learn to do something in a different way" (p. 620). Like general education, special education should challenge students with disabilities to become all they can be.

SOCIOECONOMIC STATUS AND ETHNICITY IN SCHOOLS

Children from low-income, ethnic minority backgrounds have more difficulties in school than do their middle-socioeconomic-status, non-Latinx White counterparts (Nastasi & Naser, 2021). Why? Critics argue that schools have not done a good job of educating low-income, ethnic minority students to overcome the barriers to their achievement (Banks, 2020).

In *The Shame of the Nation*, Jonathan Kozol (2005) criticized the inadequate quality and lack of resources in many U.S. schools, especially those in the poverty areas of inner cities that have high concentrations of ethnic minority children. Kozol praises teachers like Angela Lively (*above*), who keeps a box of shoes in her Indianapolis classroom for students in need.
Michael Conroy/AP Images

The Education of Students from Low-Income Backgrounds

Many children in poverty face problems that present barriers to their learning (Lampert & others, 2020). They might have parents who don't set high educational standards for them, who are incapable of reading to them, or who don't have enough money to pay for educational materials and experiences, such as books and trips to zoos and museums. They might be malnourished or live in areas where crime and violence are a way of life. One study revealed that the longer children experienced poverty, the more detrimental the poverty was to their cognitive development (Najman & others, 2009).

Compared with schools in higher-income areas, schools in low-income areas are more likely to have higher percentages of students with low achievement test scores, lower graduation rates, and smaller percentages of students going to college; to have young teachers with less experience, larger proportions of non-credentialed or unqualified teachers, and substitute teachers regularly filling in to teach; and to encourage rote learning; and they are less likely to provide adequate support for English-language learners (Crosnoe & Benner, 2015). Too few schools in low-income neighborhoods provide students with environments that are conducive to learning (Osher & others, 2020). Many of the school buildings and classrooms are old and crumbling. In sum, far too many schools in low-income neighborhoods provide students with environments that are not conducive to effective learning (Hix-Small, 2020).

Schools and school programs are the focus of some poverty interventions (Albert & others, 2020). In a longitudinal study, after a Child-Parent Center Program was implemented in high-poverty neighborhoods in Chicago to provide school-based educational enrichment and comprehensive family services for children from 3 to 9 years of age, students in these schools had higher rates of postsecondary degree completion, including more years of education, an associate's degree or higher, and master's degree (Reynolds, Ou, & Temple, 2018).

An important effort to improve the education of children growing up in low-income conditions is Teach for America (2021), a nonprofit organization that recruits and selects college graduates from universities to serve as teachers. The selected members commit to teaching for two years in a public school in a low-income community. Since the program's inception in 1990, more than 42,000 individuals have taught more than 50,000 students for Teach for America. These teachers can be, but don't have to be, education majors. In the summer before beginning to teach, they attend an intensive training program. To read about one individual who became a Teach for America instructor, see the *Connecting with Careers* interlude.

Ethnicity in Schools More than one-third of all African American and almost one-third of all Latinx students attend schools in the 47 largest city school districts in the United States, compared with only 5 percent of all non-Latinx White and 22 percent of all Asian American students. Many of these inner-city schools are still segregated, are grossly underfunded, and do not provide adequate opportunities for children to learn effectively (Cushner, McClelland, & Safford, 2022; Garcia, 2020). Thus, the effects of socioeconomic status (SES) and the effects of ethnicity are often intertwined (Banks, 2020).

The school experiences of students from different ethnic groups vary considerably (Gollnick & Chinn, 2021). African American and Latinx students are much less likely than non-Latinx White or Asian American students to be enrolled in academic, college preparatory programs and are much more likely to be enrolled in remedial and special education programs. Asian American students are far more likely than other ethnic minority groups to take advanced math and science courses in high school. African American students are twice as likely as Latinx, Native American, or non-Latinx White students to be suspended from school. The higher likelihood of African American students being suspended from school has been

Ahou Vaziri, Teach for America Instructor

Ahou Vaziri was a top student in author John Santrock's educational psychology course at the University of Texas at Dallas where she majored in Psychology and Child Development. The following year she served as a teaching intern for the educational psychology course, then applied to Teach for America and was accepted. Vaziri was assigned to work in a low-income area of Tulsa, Oklahoma, where she taught English to seventh- and eighth-graders. In her words, "The years I spent in the classroom for Teach for America were among the most rewarding experiences I have had thus far in my career. I was able to go home every night after work knowing that I truly made a difference in the lives of my students."

After her two-year teaching experience with Teach for America, Vaziri continued to work for the organization in their recruitment of college students to become Teach for America instructors. Subsequently, she moved into a role that involved developing curricula for Teach for America. Recently she earned a graduate degree in counseling from Southern Methodist University and currently is pursuing her doctoral degree in counseling psychology at the University of North Texas. During her graduate studies, she is continuing to work toward improving children's lives.

What are some features of a jigsaw classroom?
Ken Karp/McGraw Hill

attributed to more negative consequences for the same behavior displayed by non-Latinx White students (Skiba & others, 2002).

However, it is very important to note that diversity characterizes every ethnic group (Banks, 2020). For example, the higher percentage of Asian American students in advanced classes is mainly true for students with Chinese, Taiwanese, Japanese, Korean, and East Indian cultural backgrounds, but students with Hmong and Vietnamese cultural backgrounds have had less academic success.

Following are some strategies for improving relationships among ethnically diverse students:

- *Turn the class into a jigsaw classroom*. When Elliot Aronson was a professor at the University of Texas at Austin, the school system contacted him for ideas on how to reduce the increasing racial tension in classrooms. Aronson (1986) developed the concept of a "jigsaw classroom," in which students from different cultural backgrounds are placed in a cooperative group in which they have to construct different parts of a project to reach a common goal. Aronson used the term *jigsaw* because he saw that the technique resembled a group of students cooperating to put different pieces together to complete a jigsaw puzzle. How might this process work? Team sports, drama productions, and musical performances are examples of contexts in which students cooperate to reach a common goal.
- *Encourage students to have positive personal contact with diverse other students*. Contact alone does not do the job of improving relationships with diverse others. For example, busing ethnic minority students to predominantly non-Latinx White schools, or vice versa, has not reduced prejudice or improved interethnic relations. What matters is what happens after children arrive at school. Especially beneficial in improving interethnic relations is sharing one's worries, successes, failures, coping strategies, interests, and other personal information with people of other ethnicities. When this sharing happens, people tend to look at others as individuals rather than as members of a homogeneous group.

- *Encourage students to engage in perspective taking*. Exercises and activities that help students see others' perspectives can improve interethnic relations. These help students "step into the shoes" of peers who are culturally different and to discover what it feels like to be treated in fair or unfair ways.
- *Reduce bias*. Teachers can reduce bias by displaying images of children from diverse ethnic and cultural groups, selecting play materials and classroom activities that encourage cultural understanding, helping students resist stereotyping, and working with parents.
- *View the school and community as a team*. James Comer (2010) emphasizes that a community-school collaborative approach is the best way to educate children. Three important aspects of the Comer Project for Change are (1) a governance and management team that develops a comprehensive school plan, assessment strategy, and staff development plan; (2) a mental health or school support team; and (3) a parents' program. Comer says that the entire school community should have a cooperative rather than an adversarial attitude. The Comer program is currently operating in more than 600 schools in 26 states.

SCHOOLS AND THE CORONAVIRUS PANDEMIC

In 2020, the nature of K-12 and college education was drastically impacted by the coronavirus pandemic (COVID-19). Many schools abruptly switched from in-person classes to online instruction to prevent further spread of the virus. However, there was evidence that children were less likely than adults to have severe symptoms from COVID-19. Further, death rates of children due to the coronavirus were far lower than for adults.

K-12 Education A special concern during the pandemic was that some children were unable to learn as effectively through online instruction as they did in the classroom setting. This was especially likely for younger children and children with behavioral needs, such as a learning disability. Following the wave of school closings in March 2020, a survey of 477 schools found that far too many schools were basically leaving learning to chance (Gross, 2020). Also in this survey, only 1 in 3 school districts expected teachers to provide as much instruction in online formats as they would have provided in face-to-face settings, to track student engagement, and to monitor learning for all students. However, there was ongoing controversy about the health risks for teachers who were required to conduct in-person classes prior to widespread availability of COVID-19 vaccines.

How has the COVID-19 pandemic affected children's and adolescents' education and learning?
Travelerpix/Shutterstock

School closings were especially harmful for students who were dealing with challenges such as poverty, racial discrimination, and sensory and learning problems. For example, many low-income families lacked computers or Internet access. In a study conducted before and after schools closed in March 2020, student achievement in math decreased by approximately 50 percent after schools closed, with the steepest declines occurring in low-income zip code areas (Chetty & others, 2020). Further, students with sensory impairment (poor vision or hearing), as well as those with a learning disability or ADHD, often could not learn as effectively online as they did with in-person classes (Centers for Disease Control and Prevention, 2020).

Schools also provide an important context for social and emotional development. Development of peer and friendship relationships is impeded when education takes place online in the student's home. Also, in-person schooling provides access to a range of mental health and social services that are not available to students who are at home full-time.

In addition, school closings can harm children's nutritional health. Many children obtain as much as 50 percent of their daily calories at school. For children from low-income families, in-person schooling provides dependable access to affordable, healthy nutrition.

In sum, there are many reasons for maintaining classroom learning for children. That said, considerable caution needs to be taken to ensure that children can experience a safe environment in their schools. In the context of COVID-19, every safety precaution, such as daily health monitoring, social distancing, and wearing face masks, had to be carried out. Further, if the pandemic worsens considerably, a return to online instruction may be needed on a temporary basis until the severity of the pandemic lessens. When online home education is occurring, it is important for parents to monitor their children's learning as closely as possible to ensure that they are spending an adequate amount of time on learning activities.

College Education The coronavirus pandemic also dramatically changed the way college education was delivered. In mid-March 2020, a large majority of colleges shut down

in-person campus classes and abruptly switched to online instruction. Some of the same concerns about K-12 students taking online classes described above also applied to college students, such as concern that learning might be less effective and that the social aspects of college might be compromised.

During the fall of 2020, college administrations grappled with deciding whether to continue holding most or all classes online, return to in-person campus classes, or implement a hybrid format with some classes online and others in-person. A number of colleges that reinstated in-person classes had to return to online classes due to spikes in the spread of the coronavirus, especially spikes that were fueled by college students not adequately engaging in preventive measures such as social distancing, wearing face masks, and avoiding large gatherings.

Like K-12 students, traditional-age college students in their late teens and early twenties were less likely to get severe symptoms from the coronavirus, but for older college students and faculty the risk was much greater. International students also were vulnerable, with travel bans to the U.S. compounding difficulties of campus closings as well as increasing concern about housing options. Further, as with K-12 students, college students from low-income backgrounds did not always have adequate access to computers and online instruction. Further, for most colleges, the financial loss when students are not on campus was enormous, with dorms and dining facilities remaining empty when classes are given only online.

As the coronavirus pandemic began to subside, most colleges looked forward to returning to mainly in-person classes. However, the pandemic forced colleges to improve the quality of their online instruction, which could increase the percentage of classes offered online in the future.

Life is an opportunity . . . Take it.
Life is a mystery . . . Unfold it.
Life is a mission . . . Fulfill it.
Life is a struggle . . . Face it.
Life is a goal . . . Achieve it.

—Author Unknown

In any classroom, whoever the teacher is and whatever approach is used, some children achieve more than others. Why? Among the reasons for variations in achievement are characteristics of the child and sociocultural contexts related to motivation (Schunk, 2020).

EXTRINSIC AND INTRINSIC MOTIVATION

The behavioral perspective emphasizes the importance of extrinsic motivation. **Extrinsic motivation** involves doing something to obtain something else (the activity is a means to an end). Extrinsic motivation is often influenced by external incentives such as rewards and punishments (Liu & others, 2020). For example, a student may study for a test in order to obtain a good grade.

Whereas the behavioral perspective emphasizes extrinsic motivation in achievement, the cognitive perspective stresses the importance of intrinsic motivation (Chaudhuri, 2020).

Intrinsic motivation involves the internal motivation to do something for its own sake (the activity is an end in itself). For example, a student may study hard for a test because he or she enjoys the content of the course.

Let's first consider the intrinsic motivation of self-determination and personal choice. Next, we'll identify some developmental changes in intrinsic and extrinsic motivation as students move up the educational ladder. Finally, we will draw some conclusions about intrinsic and extrinsic motivation.

Self-Determination and Choice

One view of intrinsic motivation emphasizes that students want to believe that they are doing something because they want to do it, not because they are trying to achieve external success or rewards (Ryan & Deci, 2019). Students' internal motivation and intrinsic interest in school tasks increase when they have opportunities to make choices and take responsibility for their learning (Reeve & Cheon, 2021; Reeve, Cheon, & Yu, 2020).

Developmental Shifts in Intrinsic and Extrinsic Motivation

Many psychologists and educators stress that it is important for children to develop intrinsic motivation as they grow older. However, as students move from the early elementary school years to the high school years, intrinsic motivation tends to decline (Harter, 1996). In one study, the biggest drop in intrinsic motivation and the largest increase in extrinsic motivation occurred between the sixth and seventh grades (Harter, 1981).

Jacquelynne Eccles and her colleagues (Eccles & Roeser, 2015; Wigfield, Rosenzweig, & Eccles, 2017) have identified some specific changes in the school context that help to explain the decline in intrinsic motivation. Middle schools and junior high schools are more impersonal, more formal, more evaluative, and more competitive than elementary schools. Students compare themselves more with other students because they are increasingly graded in terms of their relative performance on assignments and standardized tests.

Conclusions about Intrinsic and Extrinsic Motivation

An overwhelming conclusion of motivation research is that teachers should encourage students to become intrinsically motivated (Shin & Bolkan, 2021; Zhang & others, 2021). Similarly, teachers should create learning environments that promote students' cognitive engagement and self-responsibility for learning (Schunk, 2020). That said, the real world includes both intrinsic and extrinsic motivation, and too often intrinsic and extrinsic motivation have been pitted against each other as polar opposites. In many aspects of students' lives, both intrinsic and extrinsic motivation are at work (Schunk, 2020). Further, intrinsic and extrinsic motivation can operate simultaneously. Thus, a student may work hard in a course because she enjoys the content and likes learning about it (intrinsic) and because she wants to earn a good grade (extrinsic). Keep in mind, though, that many educational psychologists suggest that relying on extrinsic motivation by itself is not a good strategy for learning.

MASTERY MOTIVATION AND MINDSET

The increasingly competitive, impersonal atmosphere of middle schools obviously does not discourage all students. For some, these characteristics represent a challenge. How students typically respond to challenges has a lot to do with how much they achieve (Reeve, Cheon, & Yu, 2020). Becoming cognitively engaged and self-motivated to improve are characteristics of individuals with mastery motivation. These individuals also have a growth mindset—a belief that they can produce positive outcomes if they put forth sufficient effort.

Mastery Motivation

Carol Dweck and her colleagues (Dweck, 2006, 2012, 2016, 2019) have found that individuals respond in two distinct ways to difficult or challenging circumstances. People who display a **mastery orientation** are task-oriented—they concentrate on learning strategies and implementing the process of achievement rather than focusing on their ability or the outcome. By contrast, those with a **helpless orientation** seem trapped by the experience of difficulty, and they attribute their difficulty to lack of ability. They frequently say such things as "I'm not very good at this," even though they might earlier have demonstrated their ability through many successes. And, once they view their behavior as failure, they often

extrinsic motivation Doing something to obtain something else (the activity is a means to an end).

intrinsic motivation Doing something for its own sake; involves factors such as self-determination and opportunities to make choices.

mastery orientation A perspective in which one is task-oriented—concerned with learning strategies and the process of achievement rather than the outcome.

helpless orientation An orientation in which one seems trapped by the experience of difficulty and attributes one's difficulty to a lack of ability.

Meredith MacGregor, shown here as a high school senior in Boulder, Colorado, was a top long-distance runner and aspired to become a scientist. She maintained a 4.0 grade point average, participated in a number of school organizations, and cofounded the AfriAid Club. She was named a *USA Today* High School Academic All-Star and was awarded the Intel Foundation Young Scientist Award (Wong Briggs, 2007). Meredith went on to obtain undergraduate, master's, and Ph.D. degrees in astronomy and astrophysics at Harvard University, followed by a post-doctoral degree in her field at Carnegie Mellon University. In 2020, she became a professor of Astrophysics and Planetary Sciences at the University of Colorado in Boulder. *What are some factors that were likely involved in Meredith's motivation to achieve?*
Kevin Moloney

The student:

- Says "I can't"
- Doesn't pay attention to teacher's instructions
- Doesn't ask for help, even when it is needed
- Does nothing (for example, stares out the window)
- Guesses or answers randomly without really trying
- Doesn't show pride in successes
- Appears bored, uninterested
- Is unresponsive to teacher's exhortations to try
- Is easily discouraged
- Doesn't volunteer answers to teacher's questions
- Maneuvers to get out of or to avoid work (for example, has to go to the nurse's office)

FIGURE **5**

BEHAVIORS THAT SUGGEST A HELPLESS ORIENTATION.

feel anxious and their performance worsens even further. Figure 5 describes some behaviors that might reflect feelings of helplessness (Stipek, 2002).

In contrast, mastery-oriented individuals often instruct themselves to pay attention, to think carefully, and to remember strategies that have worked for them in previous situations. They frequently report feeling challenged and excited by difficult tasks, rather than being threatened by them (Dweck, 2019).

Another issue in motivation involves whether to adopt a mastery or a performance orientation. Individuals with a **performance orientation** are focused on winning, rather than on an achievement outcome, and believe that happiness results from winning. Does this focus mean that mastery-oriented individuals do not like to win and that performance-oriented individuals are not motivated to experience the self-efficacy that comes from being able to take credit for one's accomplishments? No. A matter of emphasis or degree is involved, though. For mastery-oriented individuals, winning isn't everything; for performance-oriented individuals, skill development and self-efficacy take a backseat to winning.

A final point needs to be made about mastery and performance goals: They are not always mutually exclusive. Students can be both mastery- and performance-oriented, and researchers have found that mastery goals combined with performance goals often benefit students' success (Schunk, 2020).

Carol Dweck's (2006, 2012, 2016, 2019) most recent analysis of motivation for achievement stresses the importance of developing a **mindset,** which she defines as the cognitive view individuals develop for themselves. She concludes that individuals have one of two mindsets: (1) a *fixed mindset*, in which they believe that their qualities are carved in stone and cannot change; or (2) a *growth mindset*, in which they believe their qualities can change and improve through their effort. A fixed mindset is similar to a helpless orientation; a growth mindset is much like having mastery motivation.

In *Mindset*, Dweck (2006) argued that individuals' mindsets influence whether they will be optimistic or pessimistic, shape their goals and determine how hard they will strive to reach those goals, and affect many aspects of their lives, including achievement and success in school and sports. Dweck says that mindsets begin to be shaped as children and adolescents interact with parents, teachers, and coaches, who themselves have either a fixed mindset or a growth mindset.

In recent research by Dweck and her colleagues, students from lower-income families were less likely to have a growth mindset than their counterparts from wealthier families (Claro, Paunesku, & Dweck, 2016). However, the achievement of students from lower-income families who did have a growth mindset was more likely to be protected from the negative effects of poverty.

Also, Dweck and her colleagues (Dweck, 2016) recently incorporated information about the brain's plasticity into their effort to improve students' motivation to achieve and succeed. In one study, they assigned two groups of students to eight sessions of either (1) study skills instruction or (2) study skills instruction plus information about the importance of developing a growth mindset (called *incremental theory* in the research) (Blackwell, Trzesniewski, & Dweck, 2007). One of the exercises in the growth mindset group was titled "You Can Grow Your Brain," and it emphasized that the brain is like a muscle that can change and grow as it gets exercise and develops new connections. Students were informed that the more you challenge your brain to learn, the more your brain cells grow. Both groups had a pattern of declining math scores prior to the intervention. Following the intervention, math scores of the group who had received only the study skills instruction continued to decline, but the group that received the combination of study skills instruction plus the growth mindset emphasis reversed the downward trend and improved their math achievement.

In other work, Dweck has created a computer-based workshop, "Brainology," to teach students that their intelligence can change (Blackwell & Dweck, 2008). Students experience six modules about how the brain works and how to make their brain improve. After the program was tested in 20 New York City schools, students strongly endorsed the value of the computer-based brain modules. Said one student, "I will try harder because I know that the more you try the more your brain knows" (Dweck & Master, 2009, p. 137).

Recently, researchers have explored whether peer mindsets can influence a child's mindset (Sheffler & Cheung, 2020). In one study, the mindset of a student's classmates at time 1 (2 months into the school year) was linked to the student's mindset at time 2 (7 months later, near the end of the school year) (King, 2020).

Keep the growth mindset in your thoughts. Then, when you bump up against obstacles, you can turn to it . . . showing you a path into the future.

—Carol Dweck

Contemporary Psychologist, Stanford University

performance orientation An orientation in which one focuses on winning, rather than on achievement outcome; happiness is thought to result from winning.

mindset The cognitive view individuals develop for themselves that perceives their potential either as fixed or as capable of growth.

Dweck and her colleagues also recently have found that a growth mindset can prevent negative stereotypes from undermining achievement. For example, women who believe that math ability can be learned are protected from negative gender stereotyping about math (Good, Rattan, & Dweck, 2012). Also, in recent research, having a growth mindset helped to protect women's and minorities' outlook when they chose to confront expressions of bias toward them (Rattan & Dweck, 2018).

Further, in a recent study of adults, engaging in a strategic mindset was critical in achieving goals (Chen & others, 2020). This mindset involves asking oneself strategy-eliciting questions such as "What can I do to help myself?" and "Is there a way to do this even better?" in the face of challenges or inadequate progress. In this study, those with a strategic mindset used more metacognitive strategies and in turn got higher college grade point averages and made greater progress toward their professional, educational, and health goals.

A screen from Carol Dweck's Brainology program, which is designed to cultivate children's growth mindset.
Courtesy of Dr. Carol S. Dweck

Also, although some interventions have not been successful in improving students' growth mindset (Boulay & others, 2018), David Yeager and his colleagues (2018) conducted a national intervention study that involved a brief, online, direct-to-student growth mindset intervention that increased the grade point average of underachieving students and improved the challenge-seeking mental activity of higher achievers. In other recent research, the positive outcomes of the U.S. online growth mindset intervention were replicated with students in Norway (Bettinger & others, 2018).

SELF-EFFICACY

Albert Bandura's (1997, 2010a, b, 2015) social cognitive theory stresses that a critical factor in whether or not students achieve is **self-efficacy,** the belief that one can master a situation and produce favorable outcomes. Self-efficacy is the belief that "I can"; helplessness is the belief that "I cannot." Students with high self-efficacy endorse statements such as "I know that I will be able to learn the material in this class" and "I expect to be able to do well at this activity."

Dale Schunk (2020) has applied the concept of self-efficacy to many aspects of students' achievement. In his view, self-efficacy influences a student's choice of activities. Students with low self-efficacy for learning may avoid many learning tasks, especially those that are challenging. By contrast, those with high self-efficacy eagerly work at learning tasks (Schunk, 2020). High-self-efficacy students are more likely than low-self-efficacy students to expend effort and persist longer at a learning task.

GOAL SETTING, PLANNING, AND SELF-MONITORING

Setting goals, planning how to reach those goals, and engaging in self-regulation and monitoring of progress toward goals are important aspects of achievement (Eckhoff & Weiss, 2020). Self-efficacy and achievement improve when individuals set goals that are specific, proximal, and challenging (Schunk, 2020). A nonspecific, fuzzy goal is "I want to be successful." A more concrete, specific goal is "I want to make the honor roll by the end of the semester."

Students can set both long-term (distal) and short-term (proximal) goals. It is okay for individuals to set some long-term goals, such as "I want to graduate from high school" or "I want to go to college," but they also need to create short-term goals, which are steps along the way. "Getting an A on the next math test" is an example of a short-term, proximal goal. So is "Doing all of my homework by 4 p.m. Sunday."

Another good strategy is to set challenging goals (Greco & Kraimer, 2020). A challenging goal is a commitment to self-improvement. Strong interest and involvement in activities are

They can because they think they can.

Stephen Coburn/Shutterstock

sparked by challenges. Goals that are easy to reach generate little interest or effort. However, goals should be optimally matched to the individual's skill level. If goals are unrealistically high, the result will be repeated failures that lower the individual's self-efficacy.

It is not enough just to set goals. In order to achieve, it also is important to plan how to reach those goals. Being a good planner means managing time effectively, setting priorities, and being organized.

Individuals should not only plan their next week's activities but also monitor how well they are sticking to their plan. Once engaged in a task, they need to monitor their progress, judge how well they are doing on the task, and evaluate the outcomes to regulate what they do in the future. High-achieving children are often self-regulatory learners (Schunk, 2020). For example, high-achieving children monitor their learning and systematically evaluate their progress toward a goal more than low-achieving students do. Encouraging children to monitor their learning conveys the message that they are responsible for their own behavior and that learning requires their active, dedicated participation.

In addition to planning and self-regulation/monitoring, delaying gratification is an important aspect of reaching goals—especially long-term goals (Mischel, 2014). Delay of gratification involves postponing immediate rewards in order to attain larger, more valuable rewards at a later time. While adolescents may prefer to hang out with friends today rather than working on a project that is due for a class assignment later in the week, their decision not to delay gratification can have negative consequences for their academic achievement.

GRIT

Recently, as part of the continuing effort to study key aspects of achievement, there has been increasing interest in the concept of **grit**, a quality that involves passion and persistence in achieving long-term goals. Research has shown that grit is linked to academic engagement and success, including students' grade point averages. In a recent study, the persistence aspect of grit in eighth-graders was linked to their school achievement and engagement in ninth grade (Tang & others, 2019). Recent research also indicates that life purpose commitment (Hill & others, 2016), mindfulness (Raphiphatthana, Jose, & Slamon, 2018), and goal commitment (Tang & others, 2019, 2021) are antecedents of grit. And a recent study revealed that a higher level of grit (which encourages a greater commitment to goal attainment) produced better student outcomes in stronger postsecondary institutions that provided more support for students, especially in achieving on-time graduation (Goyer, Walton, & Yeager, 2021).

To determine whether you have grit, ask yourself questions such as these (Clark & Malecki, 2019):

- Do I push myself do be my best?
- Do I work hard to reach goals, no matter how long it takes to reach them?
- Once I set a goal, do I strive to overcome any challenges I might encounter?
- How passionate am I about the work I am doing?

grit Passion and persistence in achieving long-term goals.

ETHNICITY AND CULTURE

How do ethnicity and culture influence children's achievement? Of course, diversity exists within every group in terms of achievement. But Americans have been especially concerned about two questions related to ethnicity and culture. First, does the ethnicity deter children in minority groups from pursuing high achievement in school? And second, is there something about American culture that accounts for the poor performance of U.S. children in math and science?

Ethnicity Analyzing the effects of ethnicity in the United States is complicated by the fact that a disproportionate number of ethnic minorities have low socioeconomic status (Cushner, McClelland, & Safford, 2022). Disentangling the effects of SES and ethnicity can be difficult, and many investigations overlook the socioeconomic status of ethnic minority students. In many instances, when ethnicity and socioeconomic status are investigated, socioeconomic status predicts achievement better than ethnicity does. Students from middle- and upper-income families fare better than their counterparts from low-income backgrounds in a host of

achievement situations—for example, expectations for success, achievement aspirations, recognition of the importance of effort, and school achievement (Magnuson & Duncan, 2019). A longitudinal study revealed that African American children or children from low-income families benefited more than children from higher-income families when they did homework more frequently, had Internet access at home, and had a community library card (Xia, 2010). And a recent research review found that increases in family income for children in poverty were associated with increased achievement in middle school as well as greater educational attainment in adolescence and emerging adulthood (Duncan, Magnuson, & Votruba-Drzal, 2017).

Sandra Graham (1986, 1990) has conducted a number of studies that reveal stronger differences in achievement connected with socioeconomic status than with ethnicity. She is struck by how consistently middle-income African American students, like their non-Latinx White middle-income counterparts, have high achievement expectations and understand that failure is usually due to a lack of effort. An especially important factor in the lower achievement of students from low-income families regardless of their ethnic background is lack of adequate resources to support students' learning, such as an up-to-date computer in the home or even any computer at all (Schunk, 2020).

The *Connecting with Research* interlude discusses research about adolescent Black boys' expectations for themselves in terms educational achievement, and the role their parents' expectations play in their academic performance.

Cross-Cultural Comparisons International assessments indicate that students in the United States have not fared well compared with their peers in many other countries in terms of math and science performance (Desilver, 2017). In a 2019 assessment of fourth- and eighth-grade students carried out as part of the Trends in International Mathematics and Science Study (TIMSS), U.S. students placed fifteenth out of 56 countries in fourth-grade math and eighth out of 55 countries in fourth-grade science out of 55 countries (TIMSS, 2019). Also in the 2019 TIMSS study, U.S. eighth-graders placed eleventh in math out of 39 countries and eleventh in science among the 37 countries studied. The top five spots in the international assessments usually go to East Asian countries. In the four 2019 comparisons, East Asian countries held 19 of the 20 top five spots, with Singapore number one in fourth- and eighth-grade math and eighth-grade science, while Moscow City, Russia, was number one in fourth-grade science.

Despite the recent gains made by U.S. elementary school students, it is disconcerting to note that U.S. students' performance on assessments of reading, math, and science decline in comparison with students in other countries as they go from elementary school to high school. Also, U.S. students' achievement scores in math and science continue to be far below those of students in many East Asian countries.

Harold Stevenson's (1995, 2000; Stevenson, Hofer, & Randel, 1999; Stevenson & others, 1990) research has explored possible reasons for the poor performance of American students. Stevenson and his colleagues have completed five cross-cultural comparisons of students in the United States, China, Taiwan, and Japan. In these studies, Asian students consistently outperform American students. And the longer the students are in school, the wider the gap becomes between Asian and American students—the lowest difference is in first grade, the highest in eleventh grade (the highest grade studied).

To learn more about the reasons for these large cross-cultural differences, Stevenson and his colleagues spent thousands of hours observing in classrooms as well as interviewing and surveying teachers, students, and parents. They found that the Asian teachers spent more of their time teaching math than did the American teachers. For example, more than one-fourth of total classroom time in first grade was spent on math instruction in Japan, compared with only one-tenth of the time in the U.S. first-grade classrooms. Also, the Asian students were in school an average of 240 days a year, compared with 178 days in the United States.

Asian grade schools intersperse studying with frequent engagement in activities. This approach helps children maintain their attention and likely makes learning more enjoyable. Shown here are Japanese fourth-graders making wearable masks. *What are some differences in the way children in many Asian countries are taught compared with children in the United States?*

Do Parental Expectations Influence Black Boys' Math Scores?

Courtesy Lawrence Jackson

Lawrence Jackson
Key Points:
- Black male adolescents
- parental expectations
- math skills

Researcher Lawrence Jackson, who strives to be an inspiration to other Black boys/men, found extra motivation to pursue a career in psychology from his observations that there were few Black researchers at national conventions (Gradworld FSU, 2019). His research explores the factors that influence young Black boys' academic achievement. In one study, he explored the associations among what Black high school students expected of themselves regarding educational achievement, what their parents expected of them, and the student's performance on a math test (Jackson & others, 2020).

The data for the research came from the large-scale High School Longitudinal study sponsored by the National Center for Education Statistics. Among the 23,000 students from 944 high schools who participated in the study, the focus was on Black boys in ninth grade, resulting in 1,282 participants for this particular analysis. A standardized test of algebraic skills was used as a measure of current academic performance. Also, students' and parents' expectations for the future educational attainment of the student were assessed. Both the parents and students were asked the following question: "How far in school do you think he/you will get?" The response options were:

- 0 = Don't know
- 1 = Less than high school completion
- 2 = Complete high school
- 3 = Start associate's degree
- 4 = Complete associate's degree
- 5 = Start bachelor's degree
- 6 = Complete bachelor's degree
- 7 = Start master's degree

How do parents' and adolescents' educational expectations influence their education?
Digital Vision/Getty Images

- 8 = Complete master's degree
- 9 = Start professional degree
- 10 = Complete professional degree

The findings indicated that the parents' educational expectations for their children were slightly higher than what their children expected. Most parents responded between 2.64 and 9.2, with their average score at 5.92. Placed in context of the responses to the expectation question, this reveals that most parents expected their child to complete high school, and on average they basically expected the completion of a bachelor's degree. Most of the Black boys responded between 1.54 and 8.88, with their average score of 5.21. This reveals that the students were less certain than their parents that they would complete high school or attain a bachelor's degree.

Other analyses revealed that better performance on the math test was related to higher educational expectancy expressed by parents and by students. Also, when parents expected higher educational achievement from their Black sons, the sons also had higher educational expectations for themselves. In addition, higher parental expectations were associated with higher math scores, even in cases where the Black boys themselves had low educational expectations.

What activities or forms of support might teachers and schools offer to parents or extended family members to create more hope and higher expectations for adolescent Black boys' educational achievement?

In addition to the substantially greater time spent on math instruction in the Asian schools compared with the American schools, differences were found between the Asian and American parents. The American parents had much lower expectations for their children's education and achievement than did the Asian parents. Also, the American parents were more likely to believe that their children's math achievement was due to innate ability; the Asian parents were more

likely to say that their children's math achievement was the consequence of effort and training (see Figure 6). The Asian students were more likely to do math homework than were the American students, and the Asian parents were far more likely to help their children with their math homework than were the American parents (Chen & Stevenson, 1989).

Eva Pomerantz (2014) offers the following recommendations for parents of children and adolescents regarding motivation to do well in school:

- *Keep in mind that ability is not fixed and can change.* Although it is difficult and takes a lot of patience, understand that children's and adolescents' abilities can improve.
- *Be involved.* One of the most important things parents can do is to become involved in their children's and adolescents' academic life and talk often with them about what they are learning.
- *Support autonomy and self-initiative.* An important aspect of children's and adolescents' motivation to do well in school is whether they are made to feel that they are responsible for their learning and must be self-motivated.
- *Be positive.* Too often schoolwork and homework can be frustrating for children and adolescents. Interact with them in positive ways and let them know that life is often tough but that you are confident that they can do well and overcome difficulties.
- *Understand that each child and adolescent is different.* Get to know your child or adolescent—don't let them be a psychological stranger to you. Be sensitive to their unique characteristics and know that sometimes you will need to adapt to such idiosyncrasies.

There is rising concern that U.S. children are not reaching their full potential, which ultimately will hinder the success of the United States in competing with other countries (Ng & others, 2019).

Eva Pomerantz and her colleagues are conducting research on the role of parental control in children's achievement. In a study in which the title of the resulting article included the phrase "My Child Is My Report Card," Chinese mothers exerted more control (especially psychological control) over their children than did U.S. mothers (Ng, Pomerantz, & Deng, 2014). Also in this study, Chinese mothers' sense of self-worth was more contingent on their children's achievement than was the case for U.S. mothers.

Pomerantz's research reflects the term "training parents," a variation of authoritarian parenting in which many Asian parents train their children to achieve high levels of academic success. In 2011, Amy Chua's book, *Battle Hymn of the Tiger Mother,* sparked considerable interest in the role of parenting in children's achievement. Chua uses the term *Tiger Mother* to mean a mother who engages in strict disciplinary practices. In another book, *Tiger Babies Strike Back*, Kim Wong Keltner (2013) argues that the Tiger Mother parenting style can be so demanding and confining that being an Asian American child is like being locked up in an "emotional jail." She says that the Tiger Mother authoritarian style does provide some advantages for children, such as emphasizing the value of going for what you want and not taking no for an answer, but that too often the outcome is not worth the emotional costs that accompany it.

Research on Chinese-American immigrant families with first- and second-grade children has found that the children with authoritarian (highly controlling) parents are more aggressive, are more depressed, have a higher anxiety level, and show poorer social skills than children whose parents engage in non-authoritarian styles of child-rearing (Zhou & others, 2012). Qing Zhou (2013), lead author on the study just described and the director of the University of California's Culture and Family Laboratory, is conducting workshops to teach Chinese mothers positive parenting strategies such as using listening skills, praising their children for good behavior, and spending more time with their children in fun activities. Also, in a study conducted recently in China, young adolescents with authoritative parents showed better adjustment than their counterparts with authoritarian parents (Zhang & others, 2017). In sum, while an authoritarian, psychologically controlling style of parenting may be associated with higher levels of achievement, especially in Asian children, there are concerns that this parenting style also may produce more emotional difficulties in children (Pomerantz & Grolnick, 2017).

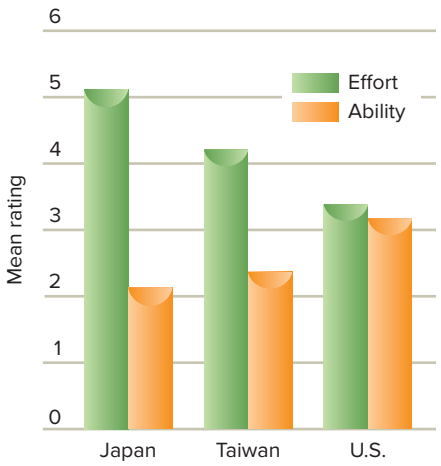

FIGURE 6

MOTHERS' BELIEFS ABOUT THE FACTORS RESPONSIBLE FOR CHILDREN'S MATH ACHIEVEMENT IN THREE COUNTRIES. In one study, mothers in Japan and Taiwan were more likely to believe that their children's math achievement was due to effort rather than innate ability, whereas U.S. mothers were more likely to believe their children's math achievement was due to innate ability (Stevenson, Lee, & Stigler, 1986). If parents believe that their children's math achievement is due to innate ability and their children are not doing well in math, the implication is that they are less likely to think their children will benefit from putting forth more effort.

- Think about several of your own past schoolmates who showed low motivation in school. Why do you think they behaved that way? What teaching strategies might have helped them?

3 Careers, Work, and Retirement

LG3 Discuss career development, work, and retirement.

Career Development | Work | Retirement

The quality of schooling that children experience and the achievement orientation they develop provide the foundation for career success and the type of work they pursue when they become adults. Choosing a career, advancing in a career, working, and coping with retirement—these are important themes in adulthood.

CAREER DEVELOPMENT

When you were a child, what were your thoughts about a career? How did your thinking about careers change as you became an adolescent? What are your thoughts now?

Developmental Changes Many children have idealistic fantasies about what they hope to be when they grow up. For example, many young children want to be superheroes, sports stars, or movie stars. In the high school years, they often have begun to think about careers in a somewhat less idealistic way. In their late teens and early twenties, their career decision making has usually turned more serious as they explore different career possibilities and zero in on the career they want to enter. In college, this focus often means choosing a major or specialization that is designed to lead to work in a specific field. By their early and mid-twenties, many individuals have completed their education or training and entered a full-time occupation. From the mid-twenties through the remainder of early adulthood, individuals often seek to establish their emerging career in a particular field. They may work hard to move up the career ladder and improve their financial standing.

Phyllis Moen (2009a) described the *career mystique*—ingrained cultural beliefs that engaging in hard work for long hours through adulthood will automatically lead to status, security, and happiness. That is, Moen found that many individuals have an idealized concept of a career path toward achieving the American dream by upward mobility through occupational ladders. However, the lockstep career mystique has never been a reality for many individuals, especially members of ethnic minority groups, women, and poorly educated adults.

connecting with careers

Grace Leaf, College/Career Counselor and College Administrator

For many years, Grace Leaf was a counselor at Spokane Community College in Washington. In 2014, she became Vice President of Instruction at Lower Columbia College in Spokane. She has a master's degree in educational leadership and is working toward a doctoral degree in educational leadership at Gonzaga University in Washington. Her job as a college counselor involved teaching orientation sessions for international students, conducting individual and group advising, and doing individual and group career planning. Grace tries to connect students with goals and values and helps them design an educational program that fits their needs and visions.

College counselors help students cope with adjustment problems, identify their abilities and interests, develop academic plans, and explore career options. Some have an undergraduate degree, others a master's degree like Grace Leaf. Some college counselors have a graduate degree in counseling; others may have an undergraduate degree in psychology or another discipline.

Grace Leaf *(center)* counsels college students at Spokane Community College about careers.

For more information about what career counselors do, see the Careers in Life-Span Development appendix.

Monitoring the Occupational Outlook and the Job Outlook for College Graduates As you explore the type of work you are likely to enjoy and in which you can succeed, it is important to become knowledgeable about different fields and companies. Occupations may have many job openings one year but fewer openings the next year as economic conditions change. Thus, it is critical to keep up with the occupational outlook in various fields. An excellent resource for doing this is the U.S. government's *Occupational Outlook Handbook*, which is revised every two years.

According to the 2020–2021 edition, solar power installers, wind turbine service technicians, home health aides, personal care aides, occupational therapy assistants, information security analysts, physician assistants, statisticians, nurse practitioners, speech-language pathologists, physical therapist assistants, and genetic counselors are the job categories that are projected to grow most rapidly through 2028 (*Occupational Outlook Handbook,* 2020–2021). Projected job growth varies widely by educational requirements. Jobs that require a college degree are expected to grow the fastest. Most of the highest-paying occupations require a college degree.

At the beginning of 2020, the job outlook for college graduates in the United States was very positive, with employers planning to increase college hiring by 5.8 percent over 2019 hiring (NACE, 2020). However, as in many other aspects of life, the outlook for college graduate employment declined steeply in March and April of 2020 with the onset of the coronavirus pandemic.

To read about the work of one individual who advises college students about careers, see the *Connecting with Careers* profile.

WORK

Work is one of the most important activities in people's lives. Our developmental coverage of work begins with adolescence and concludes with late adulthood.

Work in Adolescence One of the greatest changes in adolescents' lives in recent years has been the increased number of adolescents who work part-time and still attend school on a regular basis. Our discussion of adolescents and work focuses on the sociohistorical context

What are some advantages and disadvantages of part-time work during adolescence?
Corey Lowenstein/MCT/Landov Images

These emerging adults are college graduates who have started their own business. Emerging adults follow a diversity of work and educational pathways. *What are some of these variations in education and work that characterize emerging adults?*
Paul Bradbury/Caiaimage/Glow Images

of adolescent work and the advantages and disadvantages of part-time work at this stage of life.

Even though education keeps many of today's youth from holding full-time jobs, it has not prevented them from working part-time while going to school. In the 1970s, 1 in 4 adolescents worked part-time while going to school. Today, it is estimated that 80 to 90 percent of adolescents are employed at some point during high school (Staff, Messersmith, & Schulenberg, 2009). As adolescents go from the eighth to the twelfth grade, their likelihood of working and the average number of hours they work during the school year increase. In the eighth through tenth grades, the majority of students don't work in paid employment during the school year, but in the twelfth grade only one-fourth don't engage in paid employment during the school year. Almost 10 percent of employed twelfth-graders work more than 30 hours per week during the school year (Staff, Messersmith, & Schulenberg, 2009).

Overall, the weight of the evidence suggests that spending large amounts of time in paid labor provides limited developmental benefits for youth, and for some it is associated with risky behavior and adverse consequences for health (Larson, Wilson, & Rickman, 2009). For example, one research study found that it was not just working that affected adolescents' grades—more important was how many hours they worked per week (Greenberger & Steinberg, 1986). Tenth-graders who worked more than 14 hours a week suffered a drop in grades. Eleventh-graders worked up to 20 hours a week before their grades dropped. When adolescents spend more than 20 hours per week working, there is little time to study for tests and to complete homework assignments. Some youth, however, are engaged in challenging work activities, receive constructive supervision from adults, and experience favorable working conditions (Staff, Messersmith, & Schulenberg, 2009). For example, work may benefit adolescents in low-income, urban contexts by providing them with economic benefits and adult monitoring. These factors may increase school engagement and decrease delinquency.

Work in Emerging Adulthood The work patterns of emerging adults have changed over the last 100 years (Hamilton & Hamilton, 2009). As an increasing number of emerging adults have participated in higher education, many leave home and begin their careers at later ages. Changing economic conditions have made the job market more competitive for emerging adults and increased the demand for more highly skilled workers.

A diversity of school and work patterns characterizes emerging adults (Hamilton & Hamilton, 2009). Some emerging adults are attending college full-time; others are working full-time. Some emerging adults work full-time immediately after high school, others after they graduate from college. Many emerging adults who attend college drop out and enter the workforce before they complete their degree; some of these individuals return to college later. Some emerging adults are attending two-year colleges, others four-year colleges; and some are working part-time while going to college but others are not.

What about work during college? To read about the pluses and minuses of working during college, see the *Connecting Development to Life* interlude.

Work in Adulthood Both Sigmund Freud and the Russian Count Leo Tolstoy described love and work as the two most important things that adults need to do well. We discussed love in the chapter on "Emotional Development." Let's now explore work in the adult years.

The Work Landscape Do you work to live or live to work? Most adults spend about one-third of their lives at work. In one survey, U.S. individuals 18 years of age and older who were employed full-time worked an average of 47 hours per week, almost a full workday longer than the standard 9 to 5, five days a week schedule (Saad, 2014). In this survey, half of all individuals working full-time reported that they work more than 40 hours a week and nearly

connecting development to life

Working During College

The percentage of full-time U.S. college students who also held jobs increased from 34 percent in 1970 to 47 percent in 2008, then declined to 43 percent in in 2018 (down from a peak of 53 percent in 2000) (National Center for Education Statistics, 2020). In 2018, 81 percent of part-time U.S. college students were employed, down from 85 percent in 2000.

Working can pay for college tuition or help offset some of the costs of college, but working also can restrict students' opportunities to learn. For those who identified themselves primarily as students, one national study found that as the number of hours worked per week increased, their grades suffered (National Center for Education Statistics, 2002) (see Figure 7). Thus, college students need to carefully consider whether the number of hours they work is having a negative impact on their college success.

Of course, jobs also can contribute to a student's education. More than 1,000 colleges in the United States offer cooperative (co-op) programs, which are paid apprenticeships in specific fields. (You may not be permitted to participate in a co-op program until your junior year.) Other useful opportunities for working while going to college include internships and part-time or summer jobs relevant to your field of study. In a national survey of employers, almost 60 percent said their entry-level college hires had co-op or internship experience (Collins, 1996). Participating in these work experiences can be a key factor in landing the job you want when you graduate.

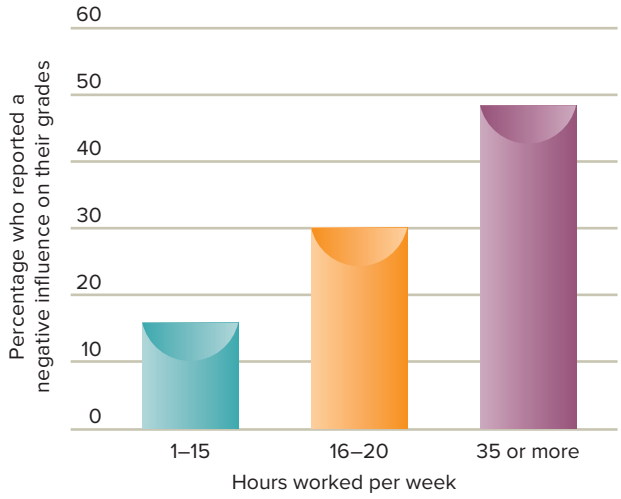

FIGURE 7

THE RELATION BETWEEN HOURS WORKED PER WEEK IN COLLEGE AND GRADES. Among students working to pay for school expenses, 16 percent of those working 1 to 15 hours per week reported that working negatively influenced their grades (National Center for Education Statistics, 2002). Thirty percent of college students who worked 16 to 20 hours per week said the same, as did 48 percent who worked 35 hours or more per week.

As unpaid internships become more common, some students complain that they are merely a way for organizations to obtain free labor. How can student interns ensure that they have a rewarding experience in spite of not being paid?

40 percent said they work 50 hours a week or more. Only 8 percent indicated that they worked less than 40 hours per week.

Work defines people in fundamental ways (Ferrell, Hirt, & Ferrell, 2020). It is an important influence on their financial standing, housing, the way they spend their time, where they live, their friendships, and their health (Bayot, Tadi, & Sharts-Hopko, 2021). Some people define their identity through their work (Hardy, 2019). Work also creates a structure and rhythm to life that is often missed when individuals do not work for an extended period. When they are unable to work, many individuals experience emotional distress and low self-esteem.

A trend in the U.S. workforce is the disappearing long-term career for an increasing number of adults, especially men in private-sector jobs. Among the reasons for the disappearance of many long-term jobs are dramatic advances in technology and companies' growing reliance on cheaper labor in other countries.

The contexts in which people work in the United States and around the world changed dramatically in 2020 as the onset of the coronavirus pandemic forced many employers to require their employees to work at home rather than in an office, classroom, or other setting to comply with social distancing and quarantine requirements in their communities. As the virus subsides, it seems likely that a growing number of employees might have an opportunity to decide whether to continue working at home, return to the company's offices, or work at home some days and in the office on other days.

An important consideration regarding work is how stressful it is (Somers & Casal, 2021; Lee & Jang, 2020). One study revealed that stressors at work were linked to arterial hypertension in employees (Lamy & others, 2014). Another recent study indicated that increases in job

What are some characteristics of work settings that are linked with employees' stress?

How has the division of responsibility for work and family changed with the increase in dual-work couples?
Halfpoint/Shutterstock

strain intensified workers' insomnia, while decreases in job strain reduced their insomnia (Halonen & others, 2017). Further, a recent study found that work-related stress and night shift work increased workers' obesity (da Silva & others, 2021). And a recent European study of 15 countries found that from 1995 to 2015 work stress increased, especially in lower-skilled occupations (Rigo & others, 2021).

Unemployment A major shift in unemployment occurred at the onset of the coronavirus in 2020. In 2019 and the first two months of 2020, the U.S. unemployment rate was at its lowest point in decades. Then it abruptly took a steep upturn in March 2020 as companies shut their doors either temporarily or permanently and let go of employees. In April and May 2020, the unemployment rate decreased as the economy began gradually reopening but remained much higher (13.3 percent in May) than it had been in the early months of 2020 (3.5 percent in February).

Unemployment produces stress regardless of whether the job loss is temporary, cyclical, or permanent (Puterman & others, 2020). Researchers have found that unemployment is linked to increased rates of physical problems (such as hypertension, heart attack, and stroke), mental problems (such as depression and anxiety), substance abuse, and marital difficulties (Bui & Wijesekera, 2019). In a recent Finnish study, rates of alcohol-related death were elevated for individuals 0 to 5 years and 11 to 20 years after they became unemployed (Junna, Moustgaard, & Martikainen, 2021).

Individuals who cope best with unemployment have financial resources to rely on, often savings or the earnings of other family members. The support of understanding, adaptable family members also helps individuals to cope with unemployment. Job counseling and self-help groups can provide practical advice on job searching, résumé writing, and interviewing skills, and also can lend emotional support.

Dual-Career Couples Dual-career couples may face special challenges finding a balance between work and family life (Booth-LeDoux, Matthews, & Wayne, 2020). If both partners are working full-time outside the home, who cleans the house or calls the repairman or takes care of the other endless details involved in maintaining a home? If the couple has children, who is responsible for making sure that the children get to school or to piano practice on time, and who signs permission slips to approve field trips, attends parent-teacher conferences, or schedules dental appointments?

Researchers have found that even though couples may strive for gender equality in dual-earner families, gender inequalities persist (Cunningham, 2009). For example, women still do not earn as much as men in the same jobs, and this inequity perpetuates gender divisions in how much time each partner spends in paid work, homemaking, and caring for children. Thus, dual-earner career decisions often are made in favor of men's greater earning power, and women end up spending more time than men in homemaking and caring for children (Moen, 2009b). In a recent study, more mothers than fathers were dissatisfied with their work-family balance and their partner's share of the load before the COVID-19 pandemic (Craig & Churchill, 2020). For some, the pandemic improved satisfaction levels, but for most they became worse.

Careers and Work in Middle Adulthood In 2019 in the United States, 81.1 percent of 45- to 54-year-olds were in the workforce (a decrease of 1.8 percent since 2000 but an increase of 1.7 percent since 2015) and 65.2 percent of 55- to 64-year-olds were in the workforce (an increase of 9.8 percent since 2000 and an increase of 1.1 percent since 2015) (Mislinski, 2019). The role of work—whether a person works in a full-time career, in a part-time job, as a volunteer, or as a homemaker—is central during middle age. Middle-aged adults may reach their peak in position and earnings but also be saddled with financial burdens from rent or mortgage, child care, medical bills, home repairs, college tuition, or bills from nursing homes for care of an elderly parent.

Leading Finnish researcher Clas-Hakan Nygard (2013) concludes from his longitudinal research that the ability to work effectively peaks during middle age because of

increased motivation, work experience, employer loyalty, and better strategic thinking. However, others conclude that for most jobs there are few differences between the work performance of young and middle-aged adults (Salthouse, 2012). Nonetheless, there is a decline in the work abilities of middle-aged adults in some careers, such as athletes and air-traffic controllers.

The progression of career trajectories in middle age is diverse, with some individuals having stable careers and others moving in and out of the labor force as they experience layoffs and unemployment. Middle-aged adults also may experience age-related discrimination in some job situations. Finding a job in midlife may be difficult because technological advances may render the midlife worker's skills outdated.

Some midlife career changes are the consequence of losing one's job; others are self-motivated. Among the work issues that some people face in midlife are recognizing limitations in career progress, deciding whether to change jobs or careers, considering whether to rebalance family and work, and planning for retirement (Brand, 2014).

A final point to make about career development in middle adulthood is that cognitive factors earlier in development are linked to occupational attainment in middle age. In one study, task persistence at 13 years of age was related to occupational success in middle age (Andersson & Bergman, 2011).

Work in Late Adulthood In 2000, 23 percent of U.S. 65- to 69-year-olds were in the work force; in 2018, this percentage had jumped to 33 percent (McCarthy, 2019). For 70- to 74-year-olds in 2000, 13 percent were in the workforce, but this percentage had increased to 19 percent in 2017 (Mislinski, 2018). The increase in the percentage of older U.S. workers has occurred more for women than men. For example, the labor force participation among women age 75 and over has risen 87 percent since 2000, while participation in the work force by men in this group has increased 45 percent (Mislinski, 2018). These increases likely are mainly driven by the need to have adequate income to meet living expenses in old age (Cahill, Giandrea, & Quinn, 2016). A recent study found that the motives and circumstances of older adults who worked beyond retirement age fell into four categories: financial, health, knowledge, and purpose in life (Sewdas & others, 2017). A recent analysis concluded that healthier, better-educated, and higher-earning older adults can work longer (United Income, 2019). Lower-income older adults are more likely to work in more physically demanding jobs, making it more difficult for them to continue working for as many years as adults whose jobs are less strenuous.

The highest rates of people working at 65 to 69 years of age occur in Asian countries, with the highest percentage (65 percent) in Indonesia in 2018 (McCarthy, 2019). The lowest rates of people working at 65 to 69 years of age are found in European countries such as France (6.7 percent) and Spain (6.4 percent) in 2018 (McCarthy, 2019).

Research suggests that U.S. workers are reasonably satisfied with their jobs and that older U.S. workers are the most satisfied of all age groups (AP-NORC Center for Public Affairs Research, 2013). However, there are significant individual variations in worker satisfaction at different points in adulthood (Antonucci & others, 2016). Further, recent research indicates that older workers not only are more satisfied at work than their younger colleagues, but also take fewer sick days and demonstrate stronger problem-solving skills (Milken Institute and Stanford Center on Longevity, 2019).

Cognitive ability is one of the best predictors of job performance in older adults (Lovden, Backman, & Lindenberger, 2017). And older workers have lower rates of absenteeism, fewer accidents, and increased job satisfaction compared with their younger counterparts (Warr, 1994). Thus the older worker can be of considerable value to a company, above and beyond the older worker's cognitive competence. Changes in federal law now allow individuals over the age of 65 to continue working. Also, remember that substantively complex work is linked with a higher level of intellectual functioning (Schooler, 2007). In sum, a cognitively stimulating work context promotes successful aging (Fisher & others, 2017).

Several recent studies also have found that older adults who work have better physical profiles than those who retire. For example, one study found that physical functioning declined faster in retirement than in full-time work for employees 65 years of age and older, with the difference not explained by absence of chronic diseases and lifestyle risks (Stenholm & others, 2014). Also, in another recent study of older adults, those who continued to work

Ninety-two-year-old Russell "Bob" Harrell (*right*) put in 12-hour days at Sieco Consulting Engineers in Columbus, Indiana. A highway and bridge engineer, he designed and planned roads. James Rice, a vice president of client services at Sieco, said that Bob wanted to learn something new every day and that he learned many life lessons from being around him. *What are some variations in work and retirement in older adults?*
Greg Sailor

What are some keys to adjusting effectively in retirement?
Bronwyn Kidd/Photodisc/Getty Images

in paid jobs had better physical and cognitive functioning than retirees (Tan & others, 2017). Further, a recent study found that all retirement pathways were associated with accelerated cognitive decline for workers in low-complexity jobs but were not linked to accelerated cognitive decline for workers in high-complexity jobs (Carr & others, 2020). And in this study, after retiring and subsequently returning to work, a modest improvement in cognitive functioning occurred.

RETIREMENT

In the past, when most people reached an accepted retirement age—usually at some point during their sixties—retirement meant a one-way exit from full-time work to full-time leisure. Increasingly, individuals are delaying retirement and moving into and out of work as the traditional lock-step process of going from full-time work to full-time retirement occurs less often (Cahill & others, 2019). Currently, there is no single dominant pattern to retirement but rather a diverse mix of pathways involving occupational identities, finances, health, and expectations and perceptions of retirement (Kojola & Moen, 2016).

Some individuals retire early, with a recent report concluding that 37 percent of U.S. workers retire earlier than they had planned (Munnell, Rutledge, & Sanzenberger, 2018). Also, a recent analysis indicated that a variety of reasons could force people to retire early, although health problems likely play the most important role, both because those in poor initial health overestimate how long they can work or because their health worsens before the age at which they planned to retire (Munnell, Rutledge, & Sanzenbacher, 2018). Further, a recent analysis of U.S. workers age 50 and older found that 50 percent were pushed out of long-term jobs before they had intended to retire (Gosselin, 2019).

Economic downturns, high unemployment rates, and potential changes in Social Security and health insurance coverage for retired individuals in the United States have made it difficult for many workers to set aside enough money for retirement. A 2017 survey indicated that only 18 percent of American workers felt very confident that they would have enough money to have a comfortable retirement (Greenwald, Copeland, & VanDerhei, 2017). However, 60 percent said they felt somewhat or very confident they would have enough money for a comfortable retirement.

Older adults who adjust best to retirement are healthy, have adequate incomes, are active, are better educated, have an extended social network including both friends and family, and usually were satisfied with their lives before they retired (Thakur, Hale, & AlSaleh, 2020). Older adults with inadequate incomes and poor health, and those who must adjust to other stressors that occur at the same time as retirement, such as the death of a spouse, have the most difficult time adjusting to retirement (Biro & Elek, 2018). In a recent study, retirement satisfaction was linked to realizing retirement plans, resilience, social integration, adopting new roles, and especially quality of family relationships (Principi & others, 2020). And in a recent study of European countries, memory decline accelerated after retirement (Macken, Riley, & Glymour, 2021).

Schools, Achievement, and Work

1 Schools

LG1 Describe the role of schools in development.

Contemporary Approaches to Student Learning and Assessment

- Contemporary approaches to student learning include the direct instruction approach and the constructivist approach. Today, many effective teachers use both a constructivist approach and a direct instruction approach.
- Increased concern by the public and government in the United States has produced extensive state-mandated testing, which has both strengths and weaknesses and is controversial. The most visible example of the increased state-mandated testing is the No Child Left Behind federal legislation.

Schools and Developmental Status

- The child-centered kindergarten emphasizes the education of the whole child, with special attention to individual variation, the process of learning, and the importance of play in development. The Montessori approach allows children to choose from a range of activities while teachers serve as facilitators.
- Developmentally appropriate practice focuses on the typical patterns of children (age appropriateness) and the uniqueness of each child (individual appropriateness). Such practice contrasts with developmentally inappropriate practice, which ignores the concrete, hands-on approach to learning.
- The U.S. government has tried to break the poverty cycle with programs such as Head Start. Model programs have been shown to have positive effects on children who live in poverty.
- Controversy surrounds early childhood education curricula. On the one side are the child-centered, constructivist advocates; on the other are those who advocate a direct instruction, academic approach. A special concern is that early elementary school education proceeds too much on the basis of providing negative feedback to children.
- The transition from elementary school to middle or junior high school can be stressful. Successful schools for young adolescents focus on individual differences, show a deep concern for what is known about early adolescence, and emphasize social as well as cognitive development.
- There are concerns about high school dropout rates and the need to improve the high school experience. The transition to college can involve a number of positive and negative experiences.

Educating Children with Disabilities

- An estimated 12.9 percent of U.S. children enrolled in public schools receive special education or related services. Slightly more than a third of students with disabilities are classified as having a learning disability. In the federal government classification, this category includes attention deficit hyperactivity disorder, or ADHD.
- Children with learning disabilities have difficulty in learning that involves understanding or using spoken or written language, and the difficulty can appear in listening, thinking, reading, writing, and spelling. A learning disability also may involve difficulty in doing mathematics. To be classified as a learning disability, the learning problem is not primarily the result of visual, hearing, or motor disabilities; intellectual disability; emotional disorders; or environmental, cultural, or economic disadvantage.
- Dyslexia is a category of learning disabilities that involves a severe impairment in the ability to read and spell.
- Attention deficit hyperactivity disorder (ADHD) is a disability in which individuals consistently show problems in one or more of these areas: (1) inattention, (2) hyperactivity, and (3) impulsivity. ADHD has been increasingly diagnosed in recent years.
- Autism spectrum disorders are severe disorders with an onset in the first three years of life; they involve abnormalities in social relationships and communication. It also is characterized by repetitive behaviors. The current consensus is that autism involves an organic brain dysfunction.

- In 1975, Public Law 94-142, the Education for All Handicapped Children Act, required that all children with disabilities be given a free, appropriate public education. This law was renamed the Individuals with Disabilities Education Act (IDEA) in 1990 and updated in 2004. IDEA includes requirements that children with disabilities receive an individualized education plan (IEP), which is a written plan that spells out a program tailored to the child, and that they be educated in the least restrictive environment (LRE), which is a setting that is as similar as possible to the one in which children without disabilities are educated. Today's trend is toward inclusion, although some aspects of inclusion have recently been criticized.

Socioeconomic Status and Ethnicity in Schools

- Children living in poverty face problems at home and at school that present barriers to learning. The school experiences of children from different ethnic groups vary considerably. A number of strategies can be adopted to improve relationships with diverse others.

Schools and the Coronavirus Pandemic

- In March 2020, the onset of the coronavirus pandemic caused abrupt changes in the way education was delivered, with the majority of in-person classes replaced with online instruction for students from kindergarten through college. There are a number of reasons why in-person classes benefit students, although the advisability of resuming in-person classes after a shutdown should be evaluated based on the potential risks to teachers, staff, and students.

2 Achievement

LG2 Explain the key aspects of achievement.

Extrinsic and Intrinsic Motivation

- Extrinsic motivation involves doing something to obtain something else (a means to an end). Intrinsic motivation involves the internal motivation to do something for its own sake (an end in itself). Overall, most experts recommend that teachers create a classroom climate in which students are intrinsically motivated to learn.
- One view of intrinsic motivation emphasizes its self-determining characteristics. Giving students some choice and providing opportunities for personal responsibility increase intrinsic motivation. When rewards are used, they should convey information about task mastery rather than external control.
- Researchers have found that as students move from the early elementary school years to high school, their intrinsic motivation declines, especially during the middle school years. Intrinsic motivation is typically favored by educational psychologists, although in many aspects of achievement, both intrinsic and extrinsic factors are at work.

Mastery Motivation and Mindset

- A mastery orientation is preferred over helpless or performance orientations in achievement situations. Mindset is the cognitive view, either fixed or growth, that individuals develop for themselves. Dweck argues that a key aspect of optimal development is guiding children and adolescents to develop a growth mindset.

Self-Efficacy

- Self-efficacy is the belief that one can master a situation and produce positive outcomes. Bandura stresses that self-efficacy is a critical factor in students' achievement. Schunk argues that self-efficacy influences a student's choice of tasks, with low-efficacy students avoiding many learning tasks.

Goal Setting, Planning, and Self-Monitoring

- Setting specific, proximal (short-term), and challenging goals benefits students' self-efficacy and achievement. Being a good planner means managing time effectively, setting priorities, and being organized. Self-monitoring is a key aspect of self-regulation that benefits student learning.

Grit

- Grit involves passion and persistence in achieving long-term goals. Grit is linked to academic engagement and success, including students' grade point averages.

Ethnicity and Culture

- In most investigations, socioeconomic status predicts achievement better than ethnicity. U.S. children do more poorly on math and science achievement tests than children in Asian countries such as China, Taiwan, and Japan.

3 Careers, Work, and Retirement

LG3 Discuss career development, work, and retirement.

Career Development

- Many young children have idealistic fantasies about a career. In the late teens and early twenties, their career thinking has usually become more serious. By their early to mid-twenties, many individuals have entered a career. In the remainder of early adulthood, they seek to establish their career and start moving up the career ladder.

Work

- Service-producing industries will account for the most jobs in America in the next decade. Jobs that require a college education will be the fastest-growing and highest-paying.
- Work defines people in fundamental ways and is a key aspect of their identity. Most individuals spend about one-third of their adult lives at work. People often become stressed if they are unable to work, but work also can produce stress, as when there is a heavy workload and time pressure.
- Working part-time during adolescence can have advantages or disadvantages, although working too many hours harms students' grades. Working during college can have negative outcomes when students work long hours, or positive outcomes when students participate in co-op programs, internships, or part-time or summer work relevant to their field of study. The work patterns of emerging adults have changed over the last 100 years, and diverse school and work patterns now characterize emerging adults.
- The nature of the transition from school to work is strongly influenced by the individual's educational level. Many emerging adults change jobs, which can involve searching or floundering. Unemployment produces stress, regardless of whether the job loss is temporary, cyclical, or permanent.
- The increasing number of women who work in careers outside the home has led to new work-related issues. There has been a considerable increase in the time men spend in household work and child care.
- For many people, midlife is a time of reflection, assessment, and evaluation of their current work and what they plan to do in the future. Midlife job or career changes can be self-motivated or forced on individuals.
- Some individuals continue a life of strong work productivity throughout late adulthood. An increasing number of older U.S. men and women are working, and since 2000 there has been a substantial increase in the percentage of older adults who remain in the workforce.

Retirement

- A retirement option for older workers is a late-twentieth-century phenomenon in the United States. The United States has extended the mandatory retirement age upward, and efforts have been made to reduce age discrimination in work-related circumstances.
- The pathways individuals follow when they reach retirement age today are less clear than in the past. Individuals adjust to retirement more smoothly if they are healthy, have adequate incomes, are active, are better educated, have an extended social network of friends and family, and are satisfied with their lives before they retire.

section six

Endings

Our life ultimately ends—when we approach life's grave sustained and soothed with unfaltering trust or rave at the close of day; when at last years steal us from ourselves, and when we are linked to our children's children's children by an invisible cable that runs from age to age. This final section contains one chapter: "Death, Dying, and Grieving."

Years following years steal something every day: At last they steal us from ourselves away.

—Alexander Pope
English Poet, 18th Century

chapter 17

DEATH, DYING, AND GRIEVING

chapter **outline**

1 The Death System and Cultural Contexts

Learning Goal 1 Describe the death system and its cultural and historical contexts.

The Death System and Its Cultural Variations
Changing Historical Circumstances

2 Defining Death and Life/Death Issues

Learning Goal 2 Evaluate issues in determining death and decisions regarding death.

Issues in Determining Death
Decisions Regarding Life, Death, and Health Care

3 A Developmental Perspective on Death

Learning Goal 3 Discuss the causes of death and suicide at different points in development.

Causes of Death
Suicide

4 Facing One's Own Death

Learning Goal 4 Explain the psychological aspects involved in facing one's own death and the contexts in which people die.

Kübler-Ross' Stages of Dying
Perceived Control and Denial
The Contexts in Which People Die

5 Coping with the Death of Someone Else

Learning Goal 5 Identify ways to cope with the death of another person.

Communicating with a Dying Person
Grieving
Making Sense of the World
Losing a Life Partner
Forms of Mourning

preview

In this final chapter, we will explore many aspects of death and dying. Among the questions that we will ask are these: What characterizes the death system and its cultural and historical contexts? How can death be defined? What are some links between development and death? How do people face their own death? How do individuals cope with the death of someone they love?

1 The Death System and Cultural Contexts

LG1 Describe the death system and its cultural and historical contexts.

The Death System and Its Cultural Variations

Changing Historical Circumstances

Sustained and soothed by an
unfaltering trust, approach
thy grave,
Like one who wraps the drapery
of his couch
About him, and lies down to
pleasant dreams.

—William Cullen Bryant
American Poet, 19th Century

Every culture has a death system, and these death systems vary across cultures. Also, when, where, and how people die have changed historically in the United States.

THE DEATH SYSTEM AND ITS CULTURAL VARIATIONS

Robert Kastenbaum (2009, 2012) emphasizes that a number of components compose the *death system* in any culture. These components include the following:

- *People*. Because death is inevitable, everyone is involved with death at some point, both their own death and the deaths of others. Some individuals have a more systematic role with death, such as those who work in the funeral industry or belong to the clergy, as well as people who work in life-threatening contexts, such as firefighters and the police.
- *Places or contexts*. These include hospitals, funeral homes, cemeteries, hospices, battlefields, and memorials (such as the Vietnam Veterans Memorial Wall in Washington, D.C.).
- *Times*. Death involves times or occasions—such as Memorial Day in the United States and the Day of the Dead in Mexico—which are set aside to honor those who have died. Also, anniversaries of disasters such as D-Day in World War II, 9/11/2001, and the 2004 tsunami in Southeast Asia that took approximately 100,000 lives are times when those who died are remembered in special ways such as ceremonies.
- *Objects*. Many objects in a culture are associated with death, including caskets and various colored objects such as clothes, armbands, and hearses. In the United States black is associated with death, but in China white is linked to death.
- *Symbols*. Symbols such as a skull and crossbones, as well as last rites in the Catholic religion and various religious ceremonies, are connected to death.

Shown here is some of the damage caused by Hurricane Michael in Mexico Beach, Florida, in October 2018, which claimed more than 30 lives. *How might people from different cultural backgrounds view and deal with the deaths caused by the hurricane?*
Scott Olson/Getty Images

Cultural variations characterize death and dying (Ribbens McCarthy & others, 2020). To live a full life and to die with glory were the prevailing goals of the ancient Greeks. Individuals are more conscious of death in times of war, famine, and plague. Whereas Americans are conditioned from early in life to live as though they were immortal, in much of the world this fiction cannot be maintained. Death crowds the streets of Calcutta in daily overdisplay, as it does the scrubby villages of Africa's Sahel. Children live with the ultimate toll of malnutrition and disease, mothers lose as many babies as survive into adulthood, and it is rare that a family remains intact for many years. Even in peasant areas where life is better, and health and maturity may be reasonable expectations, the presence of dying people in the house, the large attendance at funerals, and the daily contact with aging adults prepare the young for death and provide them with guidelines on how to die. By contrast, in the United States it is not uncommon to reach

adulthood without having talked about death or experienced the death of someone close.

Most societies throughout history have had philosophical or religious beliefs about death, and most societies have a ritual that deals with death, such as prayer (Anderson & De Souza, 2021; Saleem & Saleem, 2020). Death may be seen as a punishment for one's sins, an act of atonement, or a judgment of a just God. For some, death means loneliness; for others, death is a quest for happiness. For still others, death represents redemption, a relief from the trials and tribulations of the earthly world. Some embrace death and welcome it; others abhor and fear it. For those who welcome it, death may be seen as the fitting end to a fulfilled life. From this perspective, how we depart from life is influenced by how we have lived.

In most societies, death is not viewed as the end of existence—although the biological body has died, the spiritual body is believed to live on (Terpstra, Lehto, & Wyatt, 2021). This religious perspective is favored by most Americans as well. Cultural variations in attitudes toward death include belief in reincarnation, which is an important aspect of the Hindu and Buddhist religions (Chandradasa & Champika, 2018). In the Gond culture of India, death is believed to be caused by magic and demons. The members of the Gond culture react angrily to death. In the Tanala culture of Madagascar, death is believed to be caused by natural forces. The members of the Tanala culture show a much more peaceful reaction to death than their counterparts in the Gond culture. Figure 1 shows a ritual associated with death in South Korea.

Ahn Young-joon/AP Images

In many ways, we in the United States are death avoiders and death deniers (DeSpelder & others, 2020). This denial can take many forms:

- The tendency of the funeral industry to gloss over death and fashion lifelike qualities in the dead
- The adoption of euphemistic language for death—for example, exiting, passing on, never say die, and good for life, which implies forever
- The persistent search for a fountain of youth
- The rejection and isolation of the aged, who may remind us of death
- The adoption of the concept of a pleasant and rewarding afterlife, suggesting that we are immortal
- The medical community's emphasis on prolonging biological life rather than on diminishing human suffering

CHANGING HISTORICAL CIRCUMSTANCES

Sociohistorical variations characterize the experience of death (Dierickx & others, 2020). Individuals are more conscious of death in times of war, famine, and pandemics. In 2020–2021, the coronavirus pandemic made Americans acutely aware of death as more than half a million individuals died of the virus between the spring of 2020 and the spring of 2021.

One historical change involves the age group that death most often strikes. Two hundred years ago, nearly half of all children died before the age of 10, and one parent often died before children grew up. Today, death occurs most often among older adults. Life expectancy has increased from 47 years for a person born in 1900 to 79 years for someone born today (U.S. Census Bureau, 2020). In 1900, most people died at home, cared for by their family. As our population has aged and become more mobile, a larger number of older adults die apart from their families. In the United States today, more than 80 percent of all deaths occur in institutions or hospitals. The care of a dying older person has shifted away from the family and minimized our exposure to death and its painful surroundings.

- How extensively have death and dying been discussed in your family? Explain.

2 Defining Death and Life/Death Issues

LG2 Evaluate issues in determining death and decisions regarding death.

Issues in Determining Death

Decisions Regarding Life, Death, and Health Care

Is there one point in the process of dying that is the point at which death takes place, or is death a more gradual process? What are some decisions individuals can make about life, death, and health care?

ISSUES IN DETERMINING DEATH

Twenty-five years ago, determining whether someone was dead was simpler than it is today. The end of certain biological functions (such as breathing and blood pressure) and the rigidity of the body (rigor mortis) were considered to be clear signs of death. In the past several decades, defining death has become more complex (Dogan & Kayir, 2020; Starr, Tadi, & Pfleghaar, 2021).

Brain death is a neurological definition of death which states that a person is brain dead when all electrical activity of the brain has ceased for a specified period of time. A flat EEG (electroencephalogram) recording for a specified period of time is one criterion of brain death. The higher portions of the brain often die sooner than the lower portions. Because the brain's lower portions monitor heartbeat and respiration, individuals whose higher brain areas have died may continue breathing and have a heartbeat. The definition of brain death currently followed by most physicians includes the irreversible death of both the higher cortical functions and the lower brain stem functions (Aboubakr & Alameda, 2020).

Some medical experts argue that the criteria for death should include only higher cortical functioning. If the cortical death definition were adopted, then physicians could claim a person is dead who has no cortical functioning, even though the lower brain stem is functioning. Supporters of the cortical death policy argue that the functions we associate with being human, such as intelligence and personality, are located in the higher cortical part of the brain. They believe that when these functions are lost, the "human being" is no longer alive.

brain death A neurological definition of death—an individual is dead when all electrical activity of the brain has ceased for a specified period of time.

DECISIONS REGARDING LIFE, DEATH, AND HEALTH CARE

In cases of catastrophic illness or accidents, patients might not be able to respond adequately to participate in decisions about their medical care. To prepare for this situation, some individuals make choices earlier.

Advance Care Planning

Advance care planning refers to the process of patients thinking about and communicating their preferences about end-of-life care (Freytag & others, 2020; Moody, 2021). For many patients in a coma, it is not clear what their wishes regarding termination of treatment might be if they still were conscious. One study found that advance care planning decreased life-sustaining treatment, increased hospice use, and decreased hospital use (Brinkman-Stoppelenburg, Rietjens, & van der Heide, 2014). Recognizing that some terminally ill patients might prefer to die rather than linger in a painful or vegetative state, the organization "Choice in Dying" created the *living will*, a legal document that reflects the patient's advance care planning. However, some critics argue that completion of a living will creates a risk of an unwanted outcome: the potential for premature withdrawal of interventions (Kurin & Mirachi, 2021).

Physicians' concerns over malpractice suits and the efforts of people who support the living will concept have produced natural death legislation (Tyacke & others, 2020). Laws in all 50 states now accept an *advance directive,* such as a living will. An advance directive states such preferences as whether life-sustaining procedures should or should not be used to prolong the life of an individual when death is imminent (Gupta & others, 2021; House & Ogilvie, 2020). An advance directive must be signed while the individual still is able to think clearly (McMahan, Teliez, & Sudore, 2021). Recently, Physician Orders for Life-Sustaining Treatment (POLST), a document that is more specific than previous advance directives, was created (Hickman & others, 2021). POLST translates treatment preferences into medical orders such as those involving cardiopulmonary resuscitation, extent of treatment, and artificial nutrition via a tube (Mack & Dosa, 2020).

Euthanasia

Euthanasia ("easy death") is the act of painlessly ending the lives of individuals who are suffering from an incurable disease or severe disability (Bahnik, Vranka, & Trefna, 2021; Nicolini & others, 2020). Sometimes euthanasia is called "mercy killing." Distinctions are made between two types of euthanasia: passive and active. **Passive euthanasia** occurs when a person is allowed to die by withholding available treatment, such as withdrawing a life-sustaining device. For example, this might involve turning off a respirator or heart-lung machine or disconnecting a feeding tube. **Active euthanasia** occurs when death is deliberately induced, as when a physician or a third party ends the patient's life by administering a lethal dose of a drug.

euthanasia The act of painlessly ending the lives of persons who are suffering from incurable diseases or severe disabilities; sometimes called "mercy killing."

passive euthanasia Withholding available treatments, such as life-sustaining devices, and allowing the person to die.

active euthanasia Death induced deliberately, as when a physician or a third party ends the patient's life by administering a lethal dose of a drug.

assisted suicide Involves a physician supplying the information and/or the means of committing suicide but requires the patient to self-administer the lethal medication and to determine when and where to do this.

Technological advances in life-support devices raise the issue of quality of life (Latorre, Schmidt, & Greer, 2020). Nowhere was this more apparent than in the highly publicized case of Terri Schiavo, who suffered severe brain damage related to cardiac arrest and a lack of oxygen to the brain. She went into a coma and spent 15 years in a vegetative state. Across the 15 years, whether passive euthanasia should be implemented, or whether she should be kept in the vegetative state with the hope that her condition might improve, was debated between family members and eventually at a number of levels in the judicial system. At one point toward the end of her life in early spring 2005, a judge ordered that her feeding tube be removed. However, subsequent appeals led to its reinsertion twice. The feeding tube was removed a third and final time on March 18, 2005, and she died 13 days later. Withholding the life-support system allowed Terri Schiavo to die from passive euthanasia.

Should individuals like Terri Schiavo be kept alive in a vegetative state? The trend is toward acceptance of passive euthanasia in the case of terminally ill patients (Barnett, Cantu, & Galvez, 2020). The most widely publicized cases of active euthanasia involve *assisted suicide*. **Assisted suicide** occurs when a physician supplies the information and/or the means of committing suicide (such as giving the patient a prescription for sleeping pills or muscle relaxants and instructions regarding the dosage required to produce a coma followed by death) but requires the patient to self-administer the lethal medication and to determine when and where to do this. Thus, assisted suicide differs from active euthanasia, in which a physician causes the death of an individual through a direct action in response to a request by the person (Friesen, 2020). The most widely publicized assisted suicides were carried out by Jack Kevorkian, a Michigan physician, who assisted a number of terminally ill patients in ending their lives. After a series of trials, Kevorkian was convicted in the state of Michigan of second-degree murder and served eight years in prison for his actions. In 2007, he was released from prison at

Terri Schiavo (*right*) with her mother in an undated photo. *What issues does the Terri Schiavo case raise?*

What characterizes hospice care?
Comstock Images/Getty Images

hospice A program committed to making the end of life as free from pain, anxiety, and depression as possible. The goals of hospice contrast with those of a hospital, which are to cure disease and prolong life.

palliative care Emphasized in hospice care; involves reducing pain and suffering and helping individuals die with dignity.

age 79 for good behavior and he promised not to participate in any further assisted suicides. Kevorkian died at the age of 83.

Assisted suicide is now legal in Belgium, Canada, Finland, Luxembourg, the Netherlands, Switzerland, and the Australian state of Victoria. The United States government has no official policy on assisted suicide and leaves the decision up to each of the states. Currently, nine states allow assisted suicide–California, Colorado, Hawaii, Maine, New Jersey, Oregon, Vermont, New Mexico, and Washington, as well as Washington DC. A research review revealed that the percentage of physician-assisted deaths ranged from 0.1 to 0.2 percent in the United States and Luxembourg to 1.8 to 2.9 percent in the Netherlands (Steck & others, 2013). In this review, the percentage of assisted suicide cases reported to authorities has increased in recent years and the individuals who die through assisted suicide are most likely to be males from 60 to 75 years of age.

To what extent do people in the United States think euthanasia and assisted suicide should be legal? A Gallup poll found that 69 percent of U.S. adults said euthanasia should be legal, 51 percent said they would consider ending their own lives if faced with a terminal illness, and 50 percent reported that physician-assisted suicide is morally acceptable (Swift, 2016).

Why are euthanasia and assisted suicide so controversial? Those in favor of euthanasia and assisted suicide argue that death should be calm and dignified, not full of agony, pain, and prolonged suffering. Those against euthanasia and assisted suicide stress that it is a criminal act of murder in most states in the United States and in most countries. Many religious individuals, especially Christians, say that taking a life for any reason is against God's will and is an act of murder.

Needed: Better Care for Dying Individuals Too often, death in America is lonely, prolonged, and painful. Scientific advances sometimes have made dying harder by delaying the inevitable. Also, even though painkillers are available, too many people experience severe pain during the last days and months of life (Koksvik, 2020). A study found that 61 percent of dying patients were in pain in the last year of life and that nearly one-third had symptoms of depression and confusion prior to death (Singer & others, 2015). Many health-care professionals have not been trained to provide adequate end-of-life care or to understand its importance.

Care providers are increasingly interested in helping individuals experience a "good death" (Takahashi & others, 2021). One view is that a good death involves physical comfort, support from loved ones, acceptance, and appropriate medical care (Krishnan, 2017). For some individuals, a good death involves accepting one's impending death and not feeling like a burden to others (Carr & Luth, 2016). In a research review, the three most frequent themes described in articles on a good death involved (1) preference for dying process (94 percent of reports); (2) pain-free status (81 percent); and (3) emotional well-being (64 percent) (Meier & others, 2016).

Recent criticisms of the "good death" concept emphasize that death itself has shifted from being an event at a single point in time to being a process that takes place over years and even decades (Pollock & Seymour, 2018). Thus, say the critics, we need to move away from the concept of a "good death" as a specific event for an individual person to a larger vision of a world that not only meets the needs of individuals at their moment of death but also focuses on making their lives better during the last years and decades of their lives.

Hospice is a program committed to making the end of life as free from pain, anxiety, and depression as possible (Bhatnagar & Lagnese, 2021). Traditionally, a hospital's goals have been to cure illness and prolong life; by contrast, hospice care emphasizes **palliative care,** which involves reducing pain and suffering and helping individuals die with dignity (Lafci, Yildiz, & Pehlivan, 2021). However, U.S. hospitals have rapidly expanded their provision of palliative care in recent years. One study found that more than 85 percent of mid- to large-size U.S. hospitals had a palliative care team (Morrison, 2013). Hospice-care professionals work together to treat the dying person's symptoms, make the individual as comfortable as possible, show interest in the person and the person's family, and help everyone involved cope with death (Paice & others, 2021).

A majority of hospice care today is provided in patients' homes. In some cases, home-based care is provided by community-based health-care professionals or volunteers; in other cases, home-based care is provided by home health-care agencies or Visiting Nurse Associations (Teoli & Bhardwaj, 2021). There is a rapidly growing need for competent home health aides in hospice and palliative care (Landes & Weng, 2020; Wermuth & Tadi, 2021). Also, some hospice care is provided in free-standing, full-service hospice facilities and in hospice units in hospitals. To read about the work of a home hospice nurse, see the *Connecting with Careers* profile.

connecting with careers

Kathy McLaughlin, Home Hospice Nurse

Kathy McLaughlin is a home hospice nurse in Alexandria, Virginia. She provides care for individuals with terminal cancer, Alzheimer disease, and other diseases. There currently is a shortage of home hospice nurses in the United States.

Kathy says that she has seen too many people dying in pain, away from home, hooked up to needless machines. In her work as a home hospice nurse, she comments, "I know I'm making a difference. I just feel privileged to get the chance to meet this person who is not going to be around much longer. I want to enjoy the moment with this person. And I want them to enjoy the moment. They have great stories. They are better than novels" (McLaughlin, 2003, p. 1).

Hospice nurses like Kathy McLaughlin care for terminally ill patients and seek to make their remaining days of life as pain-free and comfortable as possible. They typically spend several hours a day in the terminally ill patient's home, serving not just as a medical caregiver but also as an emotional caregiver. Hospice nurses usually coordinate the patient's care through an advising physician.

A hospice nurse must be a registered nurse (RN) who is also certified as a hospice worker. The educational requirement is an undergraduate degree in nursing; some hospice nurses also have graduate degrees in nursing. A certified hospice nurse must have a current license as an RN, acquire a minimum of two years of experience as an RN in hospice-nursing settings, and pass an exam administered by the National Board for the Certification of Hospice Nurses.

Reflect *Your Own Personal Journey of Life*

- Have you signed an advance directive (living will)? Why or why not?

3 A Developmental Perspective on Death

LG3 Discuss the causes of death and suicide at different points in development.

Causes of Death

Suicide

Today in the United States, the deaths of older adults account for approximately two-thirds of the 2 million deaths that occur each year. Thus, what we know about death, dying, and grieving mainly is based on information about older adults. Youthful death is far less common. When, where, and how people die have changed historically in the United States (DeSpelder & Strickland, 2020).

CAUSES OF DEATH

Death can occur at any point in the human life span. Death can occur during prenatal development through miscarriages or stillborn births. Death can also occur during the birth process or in the first few days after birth, which usually happens because of a birth defect or because infants have not developed adequately to sustain life outside the uterus. *Sudden infant death syndrome* (SIDS), in which infants stop breathing (usually during the night) and die without apparent cause (Kim & Pearson-Shaver, 2021), is the leading cause of infant death in the United States, with the risk highest at 2 to 4 months of age (NICHD, 2021).

In childhood, death occurs most often because of accidents or illness. Accidental death in childhood can be the consequence of an event such as an automobile accident, drowning, poisoning, fire, or a fall from a high place. Major illnesses that cause death in children are heart disease, cancer, and birth defects.

Compared with childhood, death in adolescence is more likely to occur because of motor vehicle accidents, suicide, and homicide. Many motor vehicle accidents that cause death in adolescence are alcohol-related. We will examine suicide in greater depth shortly.

Older adults are more likely to die from chronic diseases, such as heart disease and cancer, whereas younger adults are more likely to die from accidents. Older adults' diseases often incapacitate before they kill, which produces a course of dying that slowly leads to death. Of course, many young and middle-aged adults die of illnesses such as heart disease and cancer.

developmental **connection**

Conditions, Diseases, and Disorders

Nearly 3,000 deaths of infants each year in the United States are attributed to SIDS. Connect to "Physical Development and Biological Aging."

SUICIDE

What are some of the factors that place people at increased risk for suicide? They include serious physical illnesses, mental disorders, feelings of hopelessness, social isolation, failure in school and work, loss of loved ones, serious financial difficulties, drug use, and a prior suicide attempt.

There are cultural differences in suicide (Pritchard, Iqbal, & Dray, 2020; Saiz & others, 2021). Recent cross-cultural comparisons of suicide rates for all ages of individuals found the highest suicide rate took place in the eastern European country of Lithuania, followed by South Korea, and the lowest rate occurred in South Africa (OECD, 2017). Recent cross-cultural comparisons of 15- to 19-year-olds indicated that the highest suicide rates occurred in New Zealand, followed by Iceland, and that the lowest rates occurred in Greece and Israel (OECD, 2017).

Adolescence Suicidal behavior is rare in childhood but escalates in adolescence and then increases further in emerging adulthood (Park & others, 2006). Suicide has been the third-leading cause of death in adolescents for a number of years but recently replaced homicide as the second-leading cause of death in adolescence, with accidents still being the number one cause of adolescent deaths in the United States (National Center for Health Statistics, 2020).

From 2009 to 2019, the percentage of ninth- to twelfth-grade U.S. students who think seriously about committing suicide increased from 14 to 18.8 percent (Underwood & others, 2020). In this national study conducted in 2019, 8.9 percent of U.S. students in grades 9 through 12 had attempted suicide one or more times in the past 12 months, and 2.5 percent had engaged in suicide attempts that required medical attention (Underwood & others, 2020). Almost 5,000 U.S. adolescents commit suicide each year.

The suicidal behavior of adolescents varies not only by gender but also by ethnicity (Molina & Farley, 2019). In 2019, 11 percent of U.S. female adolescents attempted suicide, compared with 6.6 percent of their male counterparts (Underwood & others, 2020). When we consider both gender and ethnicity, the highest attempted suicide rate for adolescents was among African American females (15.2 percent) and the lowest was among non-Latinx White males (6.4 percent). However, other surveys that include Native American adolescents indicate that they have the highest attempted and completed suicide rate (Goldston & others, 2008). A major risk factor for their high suicide rate involves alcohol abuse.

Just as genetic factors are associated with depression, they also are associated with suicide (Orri & others, 2020). The closer a person's genetic relationship to someone who has committed suicide, the more likely that person is to also commit suicide.

Distal, or early-life, experiences often are involved in suicide attempts as well (Cheung & others, 2020). The adolescent may have a long-standing history of family instability and unhappiness. Just as a lack of affection and emotional support, high control, and pressure for achievement by parents during childhood are related to adolescent depression, such combinations of

family experiences also are likely to show up as distal factors in adolescents' suicide attempts. In a recent study of adolescents in Hong Kong, suicide attempts were linked to child abuse (Wong & others, 2020). Also, a recent study confirmed that childhood sexual abuse is linked to later suicide attempts (Ng & others, 2018).

What is the psychological profile of the suicidal adolescent? Suicidal adolescents often have depressive symptoms (O'Rourke, Jamil, & Siddiqui, 2021). Although not all depressed adolescents are suicidal, depression is the most frequently cited factor associated with adolescent suicide (Davis & others, 2021). Also, in a recent study, a sense of hopelessness predicted an increase in suicidal ideation in depressed adolescents (Wolfe & others, 2019).

Family and peer relationships also are linked to suicide attempts (Carballo & others, 2020; Soreff, Basit, & Attia, 2021). In recent research with more than 290,000 adolescents across a four-year period, the highest stressor for suicidal ideation was peer conflict, followed by family circumstances such as conflict with parents (Kim, 2021). Also, in a recent study of 9- to 10-year-olds, family conflict was linked to children's increased suicidal ideation, and low parental monitoring was associated with suicidal ideation and suicide attempts (DeVille & others, 2020). Further, as discussed in the chapter on socioemotional development in middle and late childhood, being victimized by bullying is associated with suicide-related thoughts and behavior (O'Reilly & others, 2021). In addition, a recent cross-cultural study of more than 130,000 12- to 15-year-olds revealed that being a victim of bullying was associated with a higher probability of attempting suicide in 47 out of the 48 countries surveyed (Kovanagi & others, 2019). And a recent research review concluded that the most significant risk factors for adolescent suicide and bullying were being male, having a previous personal and/or family suicide attempt, mental health problems, substance abuse, previous physical and/or sexual abuse, low SES, being in a single-parent family, underachievement, family dysfunction, and living in a violent environment (Cuesta & others, 2021).

Recent and current stressful circumstances, such as getting poor grades in school or experiencing the breakup of a romantic relationship, may trigger suicide attempts (Liu & others, 2019; Stewart & others, 2019). For example, in a recent study, combined school difficulties (academic failure and inappropriate behavior) were associated with higher suicide risk (Ligier & others, 2020). Also, in a recent study, in 32 of 38 countries, early sexual intercourse (at 12 to 15 years of age) was linked to increased suicide attempts, and having sexual intercourse with multiple partners also increased the risk of suicide attempts (Smith & others, 2020). Further, in a recent analysis, the main factor in adolescent suicidal deaths was the occurrence of recent stressful life events (Werbart Tomblom & others, 2020).

In some instances, suicides in adolescence occur in clusters (Hawton & others, 2020). That is, when one adolescent commits suicide, other adolescents who find out about it also commit suicide. Such "copycat" suicides raise the issue of whether or not suicides should be reported in the media; a news report might plant the idea of committing suicide in other adolescents' minds.

Adulthood and Aging Suicide is increasing among U.S. adults. From 1999 to 2018, the suicide rate in the United States increased by 35 percent (National Center for Health Statistics, 2020). Suicide rates for males were 3.5 to 4.5 times the rates for females across this time frame. Suicide rates were highest for males 75 years and older and highest for females 45 to 64 years of age. In 2018, among ethnic groups, Native American/Alaska Natives had the highest suicide rate, followed by non-Latinx Whites, Latinxs, and African Americans (National Center for Health Statistics, 2020).

The older adult most likely to commit suicide is a male who lives alone, has lost his spouse, and is experiencing failing health (Heisel, 2006). One study revealed that perceiving oneself as burdensome also may be a contributing factor in suicide attempts by older adults (Corna & others, 2010). A recent study further explored the influencing and protective factors involving suicidal ideation in older adults (Huang & others, 2017). In this study, the triggers for suicidal ideation included physical discomfort, loss of respect and/or support from family, impulsive emotions due to conflicts with others, and painful memories. Psychological factors contributing to suicidal ideation included feelings of loneliness, sense of helplessness, and low self-worth. Protective factors that were linked to lower levels of suicidal ideation included a supportive network of family and friends, emotional control, and comfort from religion.

It is important to know what to do and what not to do when someone is likely to attempt suicide. Figure 2 provides some valuable guidance.

developmental **connection**
Peer Relationships
Bullying victimization is associated with suicide-related thoughts and behavior. Connect to "Peers and the Sociocultural World."

What to do

1. Ask direct, straightforward questions in a calm manner: "Are you thinking about hurting yourself?"
2. Assess the seriousness of the suicidal intent by asking questions about feelings, important relationships, who else the person has talked with, and the amount of thought given to the means to be used. If a gun, pills, a rope, or other means have been obtained and a precise plan has been developed, clearly the situation is dangerous. Stay with the person until help arrives.
3. Be a good listener and be very supportive without being falsely reassuring.
4. Try to persuade the person to obtain professional help and assist him or her in getting this help.

What not to do

1. Do not ignore the warning signs.
2. Do not refuse to talk about suicide if a person approaches you about it.
3. Do not react with humor, disapproval, or repulsion.
4. Do not give false reassurances by saying such things as "Everything is going to be OK." Also do not give out simple answers or platitudes, such as "You have everything to be thankful for."
5. Do not abandon the individual after the crisis has passed or after professional help has commenced.

4 Facing One's Own Death

LG4 Explain the psychological aspects involved in facing one's own death and the contexts in which people die.

Kübler-Ross' Stages of Dying

Perceived Control and Denial

The Contexts in Which People Die

Knowledge of death's inevitability permits us to establish priorities and structure our time accordingly. As we age, these priorities and structurings change in recognition of diminishing future time. Values concerning the most important uses of time also change. For example, when asked how they would spend six remaining months of life, younger adults described such activities as traveling and accomplishing things they previously had not done; older adults described more inner-focused activities—contemplation and meditation, for example (Kalish & Reynolds, 1976).

Most dying individuals want an opportunity to make some decisions regarding their own life and death (Kastenbaum, 2012). Some individuals want to complete unfinished business; they want to use their remaining time to resolve problems and conflicts and to put their affairs in order.

KÜBLER-ROSS' STAGES OF DYING

We are all born to die, and our lives are in a way preparation for that finality. Dealing with one's own death usually only takes front and center in a person's life when they are nearing death, but we live with that awareness throughout our lives. However, as indicated earlier in this chapter, people (especially in the United States) often tend to deny death by trying to avoid the topic altogether.

Might there be a sequence of stages we go through as we face death? Elisabeth Kübler-Ross (1969) divided the behavior and thinking of dying persons into five stages: denial and isolation, anger, bargaining, depression, and acceptance.

Denial and isolation is Kübler-Ross' first stage of dying, in which the person denies that death is really going to take place. The person may say, "No, it can't be me. It's not possible." This is a common reaction to terminal illness. However, denial is usually only a temporary defense. It is eventually replaced with increased awareness when the person is confronted with such matters as financial considerations, unfinished business, and worry about the welfare of surviving family members.

Anger is Kübler-Ross' second stage of dying, in which the dying person recognizes that denial can no longer be maintained. Denial often gives way to anger, resentment, rage, and envy. The dying person's question is "Why me?" At this point, the person becomes increasingly difficult to care for as anger may become displaced and projected onto physicians, nurses, family members, and even God. The realization of loss is great, and those who symbolize life, energy, and competent functioning are especially salient targets of the dying person's resentment and jealousy.

Bargaining is Kübler-Ross' third stage of dying, in which the person develops the hope that death can somehow be postponed or delayed. Some persons enter into bargaining or negotiation—often with God—as they try to delay their death. Psychologically, the person is saying, "Yes, me, but . . ." In exchange for a few more days, weeks, or months of life, the person promises to lead a reformed life dedicated to God or to the service of others.

Depression is Kübler-Ross' fourth stage of dying, in which the dying person perceives the certainty of his or her death. At this point, a period of depression or preparatory grief may appear. The dying person may become silent, refuse visitors, and spend much of the time crying or grieving. This behavior is normal and is an effort to disconnect the self from love objects. Attempts to cheer up the dying person at this stage should be discouraged, says Kübler-Ross, because the dying person has a need to contemplate impending death.

Acceptance is Kübler-Ross' fifth stage of dying, in which the person develops a sense of peace, an acceptance of one's fate, and—in many cases—a desire to be left alone. In this stage, feelings and physical pain may be virtually absent. Kübler-Ross describes this fifth stage as the end of the dying struggle, the final resting stage before death. A summary of Kübler-Ross' dying stages is presented in Figure 3.

What is the current evaluation of Kübler-Ross' theory about the stages of dying? According to Robert Kastenbaum (2009, 2012), there are some problems with Kübler-Ross' approach:

- The existence of the five-stage sequence has not been demonstrated by either Kübler-Ross or independent research.
- The stage interpretation neglects the patients' situation, including relationship support, specific effects of illness, family obligations, and the institutional climate in which they are interviewed.

Despite these limitations, Kübler-Ross' pioneering efforts were important in calling attention to those who are attempting to cope with life-threatening illnesses. She did much to encourage attention to the quality of life for dying persons and their families.

Because of the criticisms of Kübler-Ross' stages, some psychologists prefer to describe them not as stages but as potential reactions to dying. At any one moment, a number of emotions may wax and wane. Hope, disbelief, bewilderment, anger, and acceptance may come and go as individuals try to make sense of what is happening to them.

In facing their own death, some individuals struggle until the end, desperately trying to hang on to their lives. Acceptance of death never comes for them. Some psychologists note that the harder individuals fight to avoid the inevitable death they face and the more they deny it, the more difficulty they will have in dying peacefully and in a dignified way; other psychologists argue that not confronting death until the end may be adaptive for some individuals (Lifton, 1977).

The extent to which people have found meaning and purpose in their lives is linked with how they approach death. In a recent research review of interventions with heart failure patients, half of the studies involving interventions that emphasized meaning-making coping found significant improvements in patients' quality

denial and isolation Kübler-Ross' first stage of dying, in which the dying person denies that she or he is really going to die.

anger Kübler-Ross' second stage of dying, in which the dying person's denial gives way to anger, resentment, rage, and envy.

bargaining Kübler-Ross' third stage of dying, in which the dying person develops the hope that death can somehow be postponed.

depression Kübler-Ross' fourth stage of dying, in which the dying person perceives the certainty of her or his death. A period of depression or preparatory grief may appear.

acceptance Kübler-Ross' fifth stage of dying, in which the dying person develops a sense of peace, an acceptance of her or his fate, and, in many cases, a desire to be left alone.

FIGURE 3

KÜBLER-ROSS' STAGES OF DYING. According to Elisabeth Kübler-Ross, we go through five stages of dying: denial and isolation, anger, bargaining, depression, and acceptance. *Does everyone go through these stages, or go through them in the same order? Explain.*
skynesher/Getty Images

of life, compared with fewer than one-third of studies involving interventions that did not focus on meaning-making coping (self-care or medical adherence, for example) (Sacco, Leahey, & Park, 2019). Also, a study of 160 individuals with less than three months to live revealed that those who had found purpose and meaning in their lives felt the least despair in their final weeks, whereas dying individuals who saw no reason for living were the most distressed and wanted to hasten death (McClain, Rosenfeld, & Breitbart, 2003). In this and other studies, spirituality helped to buffer dying individuals from severe depression (Smith, McCullough, & Poll, 2003).

Do individuals become more spiritually oriented as they get closer to death? A study of more than 100 patients with advanced congestive heart failure who were studied at two times six months apart found that as the patients perceived they were closer to death, they became more focused on spiritual matters (Park, 2008).

PERCEIVED CONTROL AND DENIAL

Perceived control may work as an adaptive strategy for some older adults who face death. When individuals are led to believe they can influence and control events—such as prolonging their lives—they may become more alert and cheerful. Giving nursing home residents options for control can improve their attitudes and increase their longevity (Rodin & Langer, 1977).

Denial also may be a fruitful way for some individuals to approach death. It can be adaptive or maladaptive (Cottrell & Duggleby, 2016). Denial can be used to avoid the destructive impact of shock by delaying the necessity of dealing with one's death. Denial can insulate the individual from having to cope with intense feelings of anger and hurt. However, if denial keeps us from having a life-saving operation, it clearly is maladaptive. Denial is neither good nor bad; its adaptive qualities need to be evaluated on an individual basis.

THE CONTEXTS IN WHICH PEOPLE DIE

For dying individuals, the context in which they die is important. More than 50 percent of Americans die in hospitals, and nearly 20 percent die in nursing homes. Some people spend their final days in isolation and fear. An increasing number of people choose to die in the humane atmosphere of hospice care (Fridman & others, 2018). A Canadian study revealed that 71 percent preferred to be at home if they were near death, 15 percent preferred a hospice/palliative care facility, 7 percent a hospital, and only 2 percent a nursing home (Wilson & others, 2013).

Hospitals offer several important advantages to the dying individual—for example, professional staff members are readily available, and the medical technology present may prolong life. But a hospital may not be the best place for many people to die. Most individuals would prefer to die in their home (Bannon & others, 2018). However, even though most individuals say they would rather die at home, many feel that they will be a burden at home, that their home has limited space, and that dying at home may alter relationships. Individuals who are facing death also worry about the competency and availability of emergency medical treatment if they remain at home.

5 Coping with the Death of Someone Else

LG5 Identify ways to cope with the death of another person.

Communicating with a Dying Person | Grieving | Making Sense of the World | Losing a Life Partner | Forms of Mourning

Loss can come in many forms in our lives—divorce, a pet's death, loss of a job—but no loss is greater than that which comes through the death of someone we love and care for: a parent, child, sibling, spouse, relative, or friend. In the ratings of life's stresses that require the most adjustment, death of a spouse is given the highest number. How should we communicate with a dying individual? How do we cope with the death of someone we love?

> Man is the only animal that finds his own existence a problem he has to solve and from which he cannot escape. In the same sense man is the only animal who knows he must die.
>
> —Erich Fromm
> *American Psychotherapist, 20th Century*

COMMUNICATING WITH A DYING PERSON

Most psychologists stress that it is best for dying individuals to know that they are dying and that significant others know they are dying so they can interact and communicate with each other on the basis of this mutual knowledge. What are some of the advantages of this open awareness for the dying individual? First, dying individuals can close their lives in accord with their own ideas about proper dying. Second, they may be able to complete some plans and projects, can make arrangements for survivors, and can participate in decisions about a funeral and burial. Third, dying individuals have the opportunity to reminisce, to converse with others who have been important in their life, and to end life conscious of what life has been like. And fourth, dying individuals have more understanding of what is happening within their bodies and what the medical staff is doing to them (Kalish, 1981). In the *Connecting Development to Life* interlude, you can read further about effective communication strategies with a dying person.

connecting development to life

Communicating with a Dying Person

Effective strategies for communicating with a dying person include these:

1. **Establish your presence, be at the same eye level; don't be afraid to touch the dying person—dying individuals are often starved for human touch.**
2. **Eliminate distraction—for example, ask whether it is okay to turn off the TV. Realize that excessive small talk can be a distraction.**
3. **Dying individuals who are very frail often have little energy. If the dying person you are visiting is very frail, you may not want to visit for very long.**
4. **Don't insist that the dying person feel acceptance about death if he or she wants to deny the reality of the situation; on the other hand, don't insist on denial if the dying individual indicates acceptance.**
5. **Allow the dying person to express guilt or anger; encourage the expression of feelings.**
6. **Don't be afraid to ask the person what the expected outcome for the illness is. Discuss alternatives and unfinished business.**
7. **Sometimes dying individuals don't have access to other people. Ask the dying person whether there is anyone he or she would like to see whom you can contact.**
8. **Encourage the dying individual to reminisce, especially if you have memories in common.**
9. **Talk with the individual when she or he wishes to talk. If this is impossible, make a later appointment and keep it.**
10. **Express your regard for the dying individual. Don't be afraid to express love, and don't be afraid to say good-bye.**

What are some good strategies for communicating with a dying person?
Getty Images

How would you adjust these strategies if the dying person were very young or very old?

Everyone can master grief but he who has it.

—**William Shakespeare**
English Playwright, 17th Century

GRIEVING

Grief is a complex emotional state that is an evolving process with multiple dimensions. Our exploration of grief focuses on dimensions of grieving and how coping may vary with the type of death.

Dimensions of Grieving

Grief is the emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love. Grief is not a simple emotional state but rather a complex, evolving process with multiple dimensions (Bonanno & Malgaroli, 2020). An important dimension of grief is pining for the lost person. Pining or yearning reflects an intermittent, recurrent wish or need to recover the lost person. Another important dimension of grief is separation anxiety, which not only includes pining and preoccupation with thoughts of the deceased person but also focuses on places and things associated with the deceased, as well as crying or sighing. Grief may also involve despair and sadness, which include a sense of hopelessness and defeat, depressive symptoms, apathy, loss of meaning for activities that used to involve the person who is gone, and growing desolation (Mughal, Azhar, & Siddiqui, 2021). In a recent study, meaning was negatively associated with depression but positively associated with grief in suicide survivors (Scharer & Hibberd, 2020).

These feelings occur repeatedly shortly after a loss. As time passes, pining and protest over the loss tend to diminish, although episodes of depression and apathy may remain or increase. The sense of separation anxiety and loss may continue to the end of one's life, but most of us emerge from grief's tears, turning our attention once again to productive tasks and regaining a more positive view of life (Lichtenberg, 2017).

The grieving process is more like a roller-coaster ride than an orderly progression of stages with clear-cut time frames. The ups and downs of grief often involve rapidly changing emotions, meeting the challenges of learning new skills, detecting personal weaknesses and limitations, creating new patterns of behavior, and forming new friendships and relationships. For most individuals, grief becomes more manageable over time, with fewer abrupt highs and lows. But many grieving spouses report that even though time has brought some healing, they have never gotten over their loss. They have just learned to live with it. An estimated 80 to 90 percent of survivors experience normal or uncomplicated grief reactions that include sadness and even disbelief or considerable anguish. By six months after their loss, they accept it as a reality, are more optimistic about the future, and function competently in their everyday lives. However, six months after their loss, approximately 7 to 10 percent of bereaved individuals have difficulty moving on with their life, feel numb or detached, believe their life is empty without the deceased, and feel that the future has no meaning (Maccalum & Bryant, 2013).

What are some different types of grief?
Cohen/Ostrow/Digital Vision/Getty Images

This type of grief, which involves enduring despair that remains unresolved over an extended period of time, has been labeled **complicated grief or prolonged grief disorder** (Ghesquiere & others, 2020; Mughal, Azhar, & Siddiqui, 2021). Recently, prolonged grief disorder was included in the International Classification of Diseases (ICD-11) as a new mental health disorder (Stelzer & others, 2020). Prolonged grief usually has negative consequences for physical and mental health (Maccallum & Bryant, 2020). In a recent meta-analysis, 9.8 percent of adult bereavement cases were classified as characterized by prolonged grief disorder (Lundorff & others, 2017). In this study, the older a person was, the greater his or her risk of experiencing prolonged grief disorder. In a recent study, in the first two years of bereavement for family caregivers of terminally ill cancer patients, prolonged grief disorder preceded the onset of major depressive disorder (Tsai & others, 2020). Further, in a recent German study, difficulty in accepting the loss was the symptom most closely associated with prolonged grief disorder (Rosner & others, 2021).

Also, a recent research review concluded that death of an only child and violent killings were most likely to be associated with higher prolonged grief disorder prevalence (Djelantik & others, 2020).

A person who loses someone on whom he or she was emotionally dependent is often at greatest risk for developing prolonged grief disorder (Rodriguez Villar & others, 2012). Also, a recent 7-year longitudinal study of older adults found that those experiencing prolonged grief disorder had greater cognitive decline than their counterparts with normal grief (Perez & others, 2018). Further, another recent study revealed that individuals with complicated grief had a higher level of the personality trait neuroticism (Goetter & others, 2019). And recent research indicated that cognitive-behavioral therapy reduced prolonged grief symptoms (Lichtenthal & others, 2019).

grief The emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love.

complicated grief or prolonged grief disorder Grief that involves enduring despair and remains unresolved over an extended period of time.

Another type of grief is **disenfranchised grief,** which describes an individual's grief over a deceased person that is a socially ambiguous loss and can't be openly mourned or supported (Weaver, 2020). Examples of disenfranchised grief include a relationship that isn't socially recognized such as an ex-spouse, a hidden loss such as an abortion, and circumstances of the death that are stigmatized such as death because of AIDS. Disenfranchised grief may intensify an individual's grief because it cannot be publicly acknowledged (Garcini & others, 2019). This type of grief may be hidden or repressed for many years, only to be reawakened by later deaths.

Because of social distancing policies, many individuals who have had a close relationship with a hospitalized individual who has contracted the coronavirus cannot visit the individual and show their caring and love (Moore & others, 2020). Also, many individuals' grief over the death of a family member or friend that has recently occurred because of the coronavirus pandemic means they have not been able to be physically close to others in mourning the death through rituals and spiritual gatherings (Yahya & Khawaja, 2020). For example, funeral services are restricted, with only a few people allowed to be present while many people who been close to the deceased are expected to self-isolate and cannot attend the death ritual. As a consequence, the disenfranchised grief they experience can be especially depressing and stressful (Albuquerque, Teixeira, Rocha, 2021).

In 2020, the coronavirus pandemic dramatically changed the way people are allowed to mourn and say goodbye to loved ones. Here several close family members engage in prayer at a graveside burial in Fairfax, Virginia, in May 2020. The person who died was a 100-year-old patriarch of a very large family, and in normal times, hundreds of people would have attended the funeral. Because of the COVID-19 virus, a maximum of 10 people could attend the burial.
Andrew Caballero-Reynolds/AFP/Getty Images

Dual-Process Model of Coping with Bereavement The **dual-process model** of coping with bereavement consists of two main dimensions: (1) loss-oriented stressors and (2) restoration-oriented stressors (Stroebe & Schut, 2021; Stroebe, Schut, & Boerner, 2017). Loss-oriented stressors focus on the deceased individual and can include grief work and both positive and negative reappraisal of the loss. A positive reappraisal of the loss might include acknowledging that death brought relief at the end of suffering, whereas a negative reappraisal might involve yearning for the loved one and ruminating about the death. Restoration-oriented stressors involve the secondary stressors that emerge as indirect outcomes of bereavement (Mulligan & Karel, 2018). They can include a changing identity (such as from "wife" to "widow") and mastering additional skills (such as dealing with finances). Restoration rebuilds "shattered assumptions about the world and one's own place in it" (Stroebe, Schut, & Boerner, 2017).

In the dual-process model, effectively coping with bereavement often involves an oscillation between coping with loss and coping with restoration. Earlier models often emphasized a sequence of coping with loss through such strategies as grief work as an initial phase, followed by restoration efforts. However, in the dual-process model, coping with loss and engaging in restoration can take place concurrently. According to this model, the person coping with death might be involved in grief group therapy while settling the affairs of the loved one. Oscillation might occur in the short term during a specific day as well as across weeks, months, and even years. Although loss and restoration coping can occur concurrently, over time there often is an initial emphasis on coping with loss, followed by greater emphasis on restoration.

Recently, a variation of the dual-process model has been developed for families (Stroebe & Schut, 2017; Stroebe, Schut, & Boerner, 2017). The original model focused mainly on the bereaved individual, but many people do not grieve in isolation; most do so with immediate family members and relatives who also are affected by the loss. This recent extension of the dual-process model also focuses on such matters as reduced finances, legal consequences, and changed family relationships that must be dealt with, and seeks to integrate intrapersonal and interpersonal coping (Stroebe & Schut, 2021).

The dual-process model has been used as a conceptual framework in a number of studies involving grief and bereavement (Ross & others, 2021). In one recent study, parents who were coping with the death of their infant oscillated among various coping strategies (Currie & others, 2019). In a recent study focusing on spousal bereavement, individuals who engaged mainly in restoration-oriented coping were better adjusted both early and later in the bereavement process than those who engaged mainly in loss-oriented coping (Lundorff & others, 2019). And a recent research review concluded that the dual-process model accurately represents the bereavement experience and is effective in describing how individuals cope (Fiore, 2020).

disenfranchised grief Grief involving a deceased person that is a socially ambiguous loss that can't be openly mourned or supported.

dual-process model A model of coping with bereavement that emphasizes oscillation between loss-oriented stressors and restoration-oriented stressors.

developmental **connection**

Stress and Coping

Meaning-making coping includes drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of chronic stress such as when a loved one dies. Connect to "Moral Development, Values, and Religion."

Coping and Type of Death The impact of death on surviving individuals is strongly influenced by the circumstances under which the death occurs (Lovgren & others, 2017). Deaths that are sudden, untimely, violent, or traumatic are likely to have more intense and prolonged effects on surviving individuals and make the coping process more difficult for them (Pitman & others, 2018). Such deaths often are accompanied by post-traumatic stress disorder (PTSD) symptoms, such as intrusive thoughts, flashbacks, nightmares, sleep disturbance, and problems in concentrating (Lenferink & others, 2020). Further, a recent study of adults who had a first-degree relative die suddenly had an increased risk of suicide (Hamdan & others, 2020). And the death of a child can be especially devastating for parents (Gerrish & Bailey, 2020).

In sum, people grieve in a variety of ways. Thus, there is no ideal way to grieve. There are many different ways to feel about a deceased person and no set series of stages that the bereaved must pass through to become well adjusted. What is needed is an understanding that healthy coping with the death of a loved one involves growth, flexibility, and appropriateness within a cultural context.

MAKING SENSE OF THE WORLD

One beneficial aspect of grieving is that it stimulates many individuals to try to make sense of their world (Yang & Lee, 2021). A common occurrence is to go over again and again all of the events that led up to the death. In the days and weeks after the death, the closest family members share experiences with each other, sometimes reminiscing about family experiences.

In trying to make sense of a person's death, each individual may offer a piece of death's puzzle. "When I saw him last Saturday, he seemed to be rallying," says one family member. "Do you think it might have had something to do with his sister's illness?" remarks another. "I doubt it, but I heard from an aide that he fell going to the bathroom that morning," comments yet another. "That explains the bruise on his elbow," says the first individual. "No wonder he told me that he was angry because he could not seem to do anything right," chimes in a fourth family member. So it goes in the attempt to understand why someone who was rallying on Saturday was dead on Wednesday.

When a death is caused by an accident or a disaster, the effort to make sense of it is pursued more vigorously (Park, 2016). As added pieces of news come trickling in, they are integrated into the puzzle. The bereaved want to put the death into a perspective that they can understand—divine intervention, a curse from a neighboring tribe, a logical sequence of cause and effect, or whatever it may be.

These restaurant workers, who lost their jobs on 9/11/01, made a bittersweet return by establishing a New York restaurant to call their own. Colors, named for the many nationalities and ethnic groups among its owners, is believed to be the city's first cooperative restaurant. World-famous restaurant Windows on the World was destroyed and 73 workers killed when the Twin Towers were demolished by terrorists. The former Windows survivors at the new venture split 60 percent of the profits between themselves and donated the rest to a fund to open other cooperative restaurants.

LOSING A LIFE PARTNER

In 2019, 31 percent of women 65 years and older were widowed, compared with only 11 percent of their male counterparts (Administration on Aging, 2020). Those left behind after the death of an intimate partner often suffer profound grief and may also endure financial loss, loneliness, increased physical illness, and psychological disorders, including depression (Chen, Chow, & Tang, 2020). In a recent analysis, a spouse's death impacted women and men differently (Streeter, 2020). In this study, women experienced a 22 percent decline in income in the two years following the death of a spouse. In contrast, men's financial status stayed relatively stable but their emotional and mental health deteriorated following spousal death due to increasing rates of loneliness and depression.

In a recent cross-cultural study in the United States, England, Europe, Korea, and China, depression peaked in the first year of widowhood for men and women (Jadhav & Weir, 2018). In this study, women recovered to levels similar to married individuals in all countries, but widowed men continued to have high levels of depression 6 to 10 years post-bereavement everywhere except in Europe. A recent meta-analysis of mental disorders in widows found that depressive disorders were the most prevalent conditions, followed by anxiety disorders (Blanner Kristiansen & others, 2019). In another recent study of the mental health of widows and widowers, widows were more likely to use positive reframing, active distraction, help-seeking, and turning to God

Is Adjustment Different for Young and Middle-Aged Adults Who Lose a Life Partner?

Courtesy of Dr. Eunicia Jones

Eunicia Jones
Key Points:
- widowhood
- relationship with life partner prior to death
- adjustment and coping skills

Dr. Eunicia Jones (2021) is a marriage and family therapist who conducts research focused on health status and meaning making. She and her colleagues (Jones & others, 2019) interviewed young and middle-aged women and men whose life partner had passed away within the previous two years. Participants were asked, via a video call, to respond to open-ended questions designed to prompt each individual to tell their adjustment story.

Analysis of the transcribed data uncovered three themes that dominated the participants' overall experience.

- *Relationship quality prior to death*. Those who had been satisfied with their relationship highlighted feelings of companionship, mutual respect, and the ability to handle difficulties in acceptable ways. Those who had been dissatisfied highlighted feelings of emotional neglect and physical distance in the relationship.
- *Coping methods used*. Participants discussed ways of thinking, such as blaming their partner for their current situation, feeling guilt or self-blame around the situation, or escaping the situation by pretending their partner was simply away and would return. Participants also turned to reading books on grief and journaling, working to reconcile the event with their personal spiritual perspective, and continuing practices that they had shared as a way to feel close or connected to their partner.
- *Common concerns*. Several participants expressed sorrow over unmet expectations for the future, such as missing out on raising children together or growing old together. Many participants experienced some level of depression. They also reported feeling unsupported, isolated, and unable to discuss the loss, often because others seemed to be uncomfortable or inconvenienced by the topic.

Further analysis determined that those who had felt satisfied with their relationship prior to the death of their life partner tried to maintain a connection by continuing once-shared activities and that they experienced less severe depression and fewer feelings of guilt and blame. Those who had felt dissatisfied with their relationship prior to the death of their life partner experienced a more complicated grieving process as well as more severe and long-lasting symptoms of depression. While many of the adjustment processes of young and middle-aged individuals were similar to those of older adults, the results of this study shed new light on the experiences of younger widows and widowers who are coping with the loss, often in isolation, and building new identities.

Where might a young or middle-aged adult turn for support and guidance following the death of a life partner when family members and friends find the supportive role too uncomfortable?

for strength, while widowers were more likely to use avoidant strategies and seek connection with their late spouse (Carr, 2020). In another study, becoming widowed was associated with a 48 percent increase in risk of mortality (Sullivan & Fenelon, 2014). If their spouse's death was unexpected, the mortality risk for the surviving spouse is higher for men but not for women. And a recent research review of widowed Latinxs found that risk factors for diminished well-being were being male, financial strain, cultural stressors, having an undocumented legal status, experiencing widowhood at a younger age, and having poor physical health (Garcini & others, 2021).

Becoming widowed is likely to be especially difficult for individuals who have been happily married for a number of decades. In such circumstances, losing their spouse, who may also have been their best friend and the person with whom they lived a deeply connected life, can be an extremely emotional event that is difficult to cope with. See the *Connecting with Research* interlude regarding how the loss of a life partner can be different for younger or middle-aged adults compared with older adults.

Surviving spouses seek to cope with the loss of their spouse in various ways (Yang, 2021). In one study, widowed individuals were likely to intensify their religious and spiritual beliefs following the death of a spouse, and this increase was linked with a lower level of grief (Brown & others, 2004).

Many widows are lonely and benefit considerably from social support (King, Carr, & Taylor, 2020). The poorer and less educated they are, the lonelier they tend to be. The bereaved are also at increased risk for many health problems (Cozza & others, 2020).

developmental connection

Religion

Religion can fulfill some important psychological needs in older adults, helping them face impending death and accept the inevitable losses of old age. Connect to "Moral Development, Values, and Religion."

developmental connection

Community

For older adults, social support is linked with a reduction in the symptoms of disease and mortality. Connect to "Peers and the Sociocultural World."

Optimal adjustment after a death depends on various factors. Women do better than men largely because, in our society, women are responsible for the emotional life of a couple, whereas men usually manage the finances and material goods (Fry, 2001). Thus, women have stronger networks of friends, closer relationships with relatives, and experience in taking care of themselves psychologically (Antonucci & Webster, 2019). Older widows do better than younger widows, perhaps because the death of a partner is more expected for older women. For their part, widowers usually have more money than widows do and are far more likely to remarry.

One study found that psychological and religious factors—such as personal meaning, optimism, the importance of religion, and access to religious support—were related to the psychological well-being of older adults following the loss of a spouse (Fry, 2001). Other studies have indicated that religiosity and coping skills are related to well-being following the loss of a spouse in late adulthood (Rababa, Hayajneh, & Bani-Iss, 2021). Also, in other research, when widows engaged in volunteering to help others, their loneliness was reduced (Carr & others, 2018).

For either widows or widowers, social support helps them adjust to the death of a spouse (King, Carr, & Taylor, 2021; Sullivan & Infurna, 2020). The Widow-to-Widow program, begun in the 1960s, provides support for newly widowed women. Volunteer widows reach out to other widows, introducing them to others who may have similar problems, leading group discussions, and organizing social activities. The program has been adopted by the AARP and disseminated throughout the United States as the Widowed Persons Service. The model has since been adopted by numerous community organizations to provide support for people who are going through a difficult transition.

FORMS OF MOURNING

One decision facing the bereaved is what to do with the body. In 2018, 53.1 percent of deaths in the United States were followed by cremation—a significant increase from a cremation rate of 14 percent in 1985 and 27 percent in 2000 (Cremation Association of North America, 2020). Cremation is more popular in the Pacific region of the United States, less popular in the South. Cremation also is more popular in Canada than in the United States and most popular of all in Japan and many other Asian countries. In 2018 in Canada, 72.1 percent of deaths were followed by cremation. In the United States, the trend is away from public funerals and displaying the dead body in an open casket and toward private funerals followed by a memorial ceremony.

The funeral industry has been the source of controversy in recent years. Funeral directors and their supporters argue that the funeral provides a form of closure to the relationship with the deceased, especially when there is an open casket. Their critics claim that funeral directors

A funeral in the United States.

A crowd gathered at a cremation ceremony in Bali, Indonesia, balancing decorative containers on their heads.
Agung Parameswara/ZumaPress/Newscom

are just trying to make money and that embalming is grotesque. One way to avoid being exploited during bereavement is to purchase funeral arrangements in advance.

In some cultures, a ceremonial meal is held after a death; in others, a black armband is worn for one year following a death. The family and the community have important roles in mourning in some cultures. Two of those cultures are the Amish and traditional Judaism (Worthington, 1989).

The Amish are a conservative group with more than 300,000 members in North America, including 31 U.S. states and four Canadian provinces. In addition, there are several small Amish settlements in South and Central America. The Amish live in a family-oriented society in which family and community support is essential for survival. Today, they live at the same unhurried pace as did their ancestors, using horses instead of cars and facing death with the same steadfast faith as their forebears. At the time of death, close neighbors assume the responsibility of notifying others of the death. The Amish community handles virtually all aspects of the funeral.

The funeral service is held in a barn in warmer months and in a house during colder months. Calm acceptance of death, influenced by a deep religious faith, is an integral part of the Amish culture. Following the funeral, a high level of support is given to the bereaved family for at least a year. Visits to the family, special scrapbooks and handmade items for the family, new work projects started for the widow, and quilting days that combine fellowship and productivity are among the supports given to the bereaved family. A profound example of the Amish culture's religious faith and acceptance of death occurred after Charles Roberts shot and killed five Amish schoolgirls and then apparently took his own life in October 2006 in the small town of Nickel Mines in Bart Township, Pennsylvania. Soon after the murders and suicide, members of the Amish community visited the widow of the murderer and offered their support and forgiveness.

A funeral procession of horse-drawn buggies on their way to the burial of five young Amish girls who were murdered in October 2006. A remarkable aspect of their mourning involved the outpouring of support and forgiveness they gave to the widow of the murderer.

Gil Cohen Magen/Reuters/Landov Images

The family and community also have specific and important roles in mourning in traditional Judaism. The program of mourning is divided into graduated time periods, each with its appropriate practices. The observance of these practices is required of the spouse and the immediate blood relatives of the deceased. The first period is *aninut,* the period between death and burial—which must take place within one day. The next two periods make up *avelut,* or mourning proper. The first of these is *shivah,* a period of seven days, which commences with the burial. It is followed by *sheloshim,* the 30-day period following the burial, including shivah. At the end of sheloshim, the mourning process is considered over for all but one's parents. For parents, mourning continues for 11 months, although observances are minimal.

The seven-day period of the shivah is especially important in traditional Judaism. The mourners, sitting together as a group for an extended period, have an opportunity to project their feelings to the group as a whole. Visits from others during shivah may help the mourner deal with feelings of guilt. After shivah, the mourner is encouraged to resume normal social interaction. In fact, it is customary for the mourners to walk together a short distance as a symbol of their return to society. In its entirety, the elaborate mourning system of traditional Judaism is designed to promote personal growth and to reintegrate bereaved individuals into the community.

Some Final Comments We have arrived at the end of *A Topical Approach to Life-Span Development*. I hope this edition and course have been a window to the life span of the human species and a window to your own personal journey in life.

Our study of the human life span has been long and complex. You have read about many physical, cognitive, and socioemotional changes that take place from conception through death. This is a good time to reflect on what you have learned. Which theories, studies, and ideas were especially interesting to you? What did you learn about your own development?

I wish you all the best in the remaining years of your journey though the human life span.

reach your **learning goals**

Death, Dying, and Grieving

1 The Death System and Cultural Contexts

LG1 Describe the death system and its cultural and historical contexts.

The Death System and Its Cultural Variations

- In Kastenbaum's view, every culture has a death system that involves people, places, times, objects, and symbols.
- Most societies throughout history have had philosophical or religious beliefs about death, and most societies have rituals that deal with death. Most cultures do not view death as the end of existence—spiritual life is thought to continue. The United States has been described as more of a death-denying and death-avoiding culture than most cultures.

Changing Historical Circumstances

- When, where, and why people die have changed historically. Today, death occurs most often among older adults. More than 80 percent of all deaths in the United States now occur in a hospital or other institution; our exposure to death in the family has been minimized.

2 Defining Death and Life/Death Issues

LG2 Evaluate issues in determining death and decisions regarding death.

Issues in Determining Death

- Twenty-five years ago, determining whether someone was dead was simpler than it is today. Brain death is a neurological definition which states that a person is brain dead when all electrical activity of the brain has ceased for a specified period of time. Medical experts debate whether this definition should include both the higher and lower brain functions or just the higher cortical functions. Most physicians use the cessation of brain function (both higher and lower) as a standard for determining death.

Decisions Regarding Life, Death, and Health Care

- Decisions regarding life, death, and health care can involve advance care planning, euthanasia, and hospice care.
- Advance care planning can involve living wills and advance directives. Physician Orders for Life-Sustaining Treatment (POLST) is a more detailed and specific document than previous advance directives.
- Euthanasia is the act of painlessly ending the life of a person who is suffering from an incurable disease or disability. Distinctions are made between active and passive euthanasia.
- Hospice care emphasizes reducing pain and suffering, rather than prolonging life.

3 A Developmental Perspective on Death

LG3 Discuss the causes of death and suicide at different points in development.

Causes of Death

- Although death is more likely to occur in late adulthood, it can come at any point in development. In children and younger adults, accidents are the most frequent cause of death. In older adults, death is most often caused by chronic diseases.

Suicide

- Among the factors that place people at risk for suicide are serious physical illnesses, feelings of hopelessness, social isolation, failure in school and work, loss of loved ones, serious financial difficulties, and depression.
- Suicidal behavior is rare in childhood but escalates in adolescence. Both earlier and later experiences can influence suicide. U.S. suicide rates remain fairly stable in early and middle adulthood, then increase in late adulthood.

4 Facing One's Own Death

LG4 Explain the psychological aspects involved in facing one's own death and the contexts in which people die.

Kübler-Ross' Stages of Dying

- Kübler-Ross proposed five stages of dying: denial and isolation, anger, bargaining, depression, and acceptance. Critics emphasize that many individuals don't go through the stages in the order Kübler-Ross proposed.

Perceived Control and Denial

- Perceived control and denial may work together as an adaptive orientation for the dying individual. Denial can be adaptive or maladaptive, depending on the circumstances.

The Contexts in Which People Die

- Most deaths in the United States occur in hospitals; this setting has advantages and disadvantages. Most individuals say they would rather die at home, but they worry that they will be a burden and they are concerned about the availability of medical care.

5 Coping with the Death of Someone Else

LG5 Identify ways to cope with the death of another person.

Communicating with a Dying Person

- Most psychologists recommend communicating openly with the dying. Communication should not dwell on pathology or preparation for death but should emphasize the dying person's strengths.

Grieving

- Grief is the emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love. Grief is multidimensional and in some cases may last for years.
- Complicated grief or prolonged grief disorder involves enduring despair that remains unresolved over an extended period of time.
- In the dual-process model of coping with bereavement, oscillation occurs between two dimensions: loss-oriented stressors and restoration-oriented stressors.
- Grief and coping vary with the type of death. There are cultural variations in grieving.

Making Sense of the World

- The grieving process may stimulate individuals to strive to make sense out of their world; each individual may contribute a piece to death's puzzle.

Losing a Life Partner

- Usually the most difficult loss is the death of a spouse. The bereaved are at risk for many health problems, although there are variations in the distress experienced by a surviving spouse. Social support benefits widows and widowers.

Forms of Mourning

- Forms of mourning vary across cultures. In 2015, almost 49 percent of corpses were cremated. An important aspect of mourning in many cultures is the funeral. In recent years, the funeral industry has been the focus of controversy. In some cultures, a ceremonial meal is held after a death.

glossary

A

A-not-B error This error occurs when infants make the mistake of selecting the familiar hiding place (A) of an object rather than its new hiding place (B) as they progress into substage 4 in Piaget's sensorimotor stage.

acceptance Kübler-Ross' fifth stage of dying, in which the dying person develops a sense of peace, an acceptance of her or his fate, and, in many cases, a desire to be left alone.

accommodation Piagetian concept of incorporating new experiences into existing schemes.

accommodation of the eye The eye's ability to focus and maintain an image on the retina.

active euthanasia Death induced deliberately, as when a physician or a third party ends the patient's life by administering a lethal dose of a drug.

active (niche-picking) genotype-environment correlations Correlations that exist when children seek out environments they find compatible and stimulating.

activity theory The theory that the more active and involved older adults are, the more likely they are to be satisfied with their lives.

adolescent egocentrism The heightened self-consciousness of adolescents, which is reflected in adolescents' beliefs that others are as interested in them as they are themselves, and in adolescents' sense of personal uniqueness and invincibility.

adoption study A study in which investigators seek to discover whether, in behavior and psychological characteristics, adopted children are more like their adoptive parents, who provided a home environment, or more like their biological parents, who contributed their heredity. Another form of the adoption study compares adoptive and biological siblings.

aerobic exercise Sustained activity that stimulates heart and lung functioning.

affectionate love Also called companionate love, this type of love occurs when individuals desire to have another person near and have a deep, caring affection for the person.

affordances Opportunities for interaction offered by objects that fit within our capabilities to perform activities.

ageism Prejudice against people because of their age, especially prejudice against older adults.

altruism An unselfish interest and voluntary effort in helping another person.

Alzheimer disease A progressive, irreversible brain disorder characterized by a gradual deterioration of memory, reasoning, language, and eventually, physical function.

amygdala A part of the brain's limbic system that is the seat of emotions such as anger.

androgens A class of sex hormones—an important one of which is testosterone—that primarily promotes the development of male genitals and secondary sex characteristics.

androgyny The presence of positive masculine and feminine characteristics in the same individual.

anger Kübler-Ross' second stage of dying, in which the dying person's denial gives way to anger, resentment, rage, and envy.

anger cry A cry similar to the basic cry but with more excess air forced through the vocal cords.

animism A facet of preoperational thought—the belief that inanimate objects have lifelike qualities and are capable of action.

anorexia nervosa An eating disorder that involves the relentless pursuit of thinness through starvation.

anxious attachment style An attachment style that describes adults who demand closeness, are less trusting, and are more emotional, jealous, and possessive.

Apgar Scale A widely used method to assess the health of newborns at one and five minutes after birth; it evaluates an infant's heart rate, respiratory effort, muscle tone, body color, and reflex irritability.

aphasia A loss or impairment of language processing resulting from damage to Broca's area or Wernicke's area.

artificial intelligence (AI) Scientific field that focuses on creating machines capable of performing activities that require intelligence when they are done by people.

assimilation Piagetian concept in which children use existing schemes to incorporate new information.

assisted suicide Involves a physician supplying the information and/or the means of committing suicide but requires the patient to self-administer the lethal medication and to determine when and where to do this.

attachment A close emotional bond between two people.

attention Focusing of mental resources.

attention deficit hyperactivity disorder (ADHD) A disability in which children consistently show one or more of the following characteristics: (1) inattention, (2) hyperactivity, and (3) impulsivity.

authoritarian parenting A restrictive, punitive style in which parents exhort the child to follow their directions and to respect their work and effort. Firm limits are placed on the child, and little verbal exchange is allowed.

authoritative parenting A style that encourages children to be independent but still places limits and controls on children's actions; extensive verbal give-and-take is allowed, and parents are warm and nurturant toward the child.

autism spectrum disorders (ASDs) Disorders involving problems in social interaction, verbal and nonverbal communication, and repetitive behaviors that are linked to organic brain dysfunction.

automaticity The ability to process information with little or no effort.

autonomous morality The second stage of moral development in Piaget's theory, displayed by children about 10 years of age and older. At this stage, children become aware that rules and laws are created by people and that in judging an action they should consider the actor's intentions as well as the consequences.

average children Children who receive an average number of both positive and negative nominations from their peers.

avoidant attachment style An attachment style that describes adults who are hesitant about getting involved in romantic relationships and, once in a relationship, tend to distance themselves from their partner.

B

balance theory of wisdom Sternberg's theory that wisdom consists of using one's intelligence, creativity, common sense, and knowledge in a balanced, ethical manner. Individuals should apply their wisdom in a balanced way across intrapersonal, interpersonal, and extrapersonal contexts to promote the common good.

bargaining Kübler-Ross' third stage of dying, in which the dying person develops the hope that death can somehow be postponed.

basic cry A rhythmic pattern usually consisting of a cry, a briefer silence, a shorter inspiratory whistle that is higher pitched than the main cry, and then a brief rest before the next cry.

Bayley Scales of Infant Development Widely used scales, developed by Nancy Bayley, for assessing infant development. The current version, the Bayley-III, has five scales: cognitive, language, motor, socio-emotional, and adaptive; the first three are administered to the infant, the latter two to the caregiver.

behavior genetics The field that seeks to discover the influence of heredity and environment on individual differences in human traits and development.

bicultural identity Identifying both with one's own ethnic minority group and with the majority culture.

Big Five factors of personality The view that personality is made up of five factors: openness to experience, conscientiousness, extraversion, agreeableness, and neuroticism.

binge eating disorder (BED) Involves frequent binge eating without compensatory behavior like the purging that characterizes bulimics.

biological processes Processes that produce changes in an individual's physical nature.

bisexuality Romantic or sexual attraction to more than one gender.

bonding The formation of a close connection, especially a physical bond between parents and their newborn in the period shortly after birth.

brain death A neurological definition of death—an individual is dead when all electrical activity of the brain has ceased for a specified period of time.

brainstorming Technique in which individuals are encouraged to come up with creative ideas in a group, play off each other's ideas, and say practically whatever comes to mind that is relevant to a particular issue.

Broca's area An area of the brain's left frontal lobe that is involved in producing words.

Bronfenbrenner's ecological theory Bronfenbrenner's environmental systems theory that focuses on five environmental systems: microsystem, mesosystem, exosystem, macrosystem, and chronosystem.

bulimia nervosa An eating disorder in which the individual consistently follows a binge-and-purge eating pattern.

C

care perspective The moral perspective of Carol Gilligan; views people in terms of their connectedness with others and emphasizes interpersonal communication, relationships with others, and concern for others.

case study An in-depth look at a single individual.

cataracts A thickening of the lens of the eye that causes vision to become cloudy, opaque, and distorted.

cellular clock theory Leonard Hayflick's theory that the number of times human cells can divide is about 75 to 80. As we age, our cells become less able to divide.

centration Focusing attention on one characteristic to the exclusion of all others.

cephalocaudal pattern The sequence in which the fastest growth occurs at the top of the body—the head—with physical growth in size, weight, and feature differentiation gradually working from top to bottom.

character education A direct moral education program in which students are taught moral literacy to prevent them from engaging in immoral behavior.

child abuse The term used most often by the public and many professionals to refer to both abuse and neglect.

child maltreatment The term increasingly used by developmentalists in referring not only to abuse and neglect but also to diverse conditions.

child neglect Failure to provide for a child's basic needs, including physical, educational, or emotional needs.

child-centered kindergarten Education that involves the whole child by considering both the child's physical, cognitive, and socioemotional development and the child's needs, interests, and learning styles.

child-directed speech Language spoken in a higher pitch than normal, with simple words and sentences.

chromosomes Threadlike structures made up of deoxyribonucleic acid, or DNA.

chronic disorders Disorders characterized by slow onset and long duration.

climacteric The midlife transition during which fertility declines.

cliques Small groups that range from 2 to 12 individuals and average about 5 or 6 individuals. Clique members usually are of the same age and same sex and often engage in similar activities, such as belonging to a club or participating in a sport.

cognitive mechanics The "hardware" of the mind, reflecting the neurophysiological architecture of the brain as developed through evolution. Cognitive mechanics involves the speed and accuracy of the processes involving sensory input, visual and motor memory, discrimination, comparison, and categorization.

cognitive pragmatics The culture-based "software" of the mind. Cognitive pragmatics includes reading and writing skills, language comprehension, educational qualifications, professional skills, and the self-knowledge and life skills that help us to master or cope with life.

cognitive processes Processes that involve changes in an individual's thought, intelligence, and language.

cohabitation Living together in a sexual relationship without being married.

cohort effects Characteristics attributable to a person's time of birth, era, or generation but not to actual age.

collectivism Emphasizing values that serve the group by subordinating personal goals to preserve group integrity, supporting interdependence of members, and promoting harmonious relationships.

commitment A personal investment in identity.

complicated grief or prolonged grief disorder Grief that involves enduring despair and remains unresolved over an extended period of time.

concepts Cognitive groupings of similar objects, events, people, or ideas.

concrete operational stage The third Piagetian stage, which lasts from approximately 7 to 11 years of age; children can perform concrete operations, and logical reasoning replaces intuitive reasoning as long as the reasoning can be applied to specific or concrete examples.

conduct disorder Age-inappropriate actions and attitudes that violate family expectations, society's norms, and the personal or property rights of others.

connectedness Characteristic consisting of two dimensions: mutuality, which is sensitivity to and respect for others' views; and permeability, which is openness to others' views.

conscience The component of the superego that punishes the child for behaviors disapproved of by parents by making the child feel guilty and worthless.

conservation The awareness that altering the appearance of an object or a substance does not change its basic properties.

constructive play Combination of sensorimotor/practice play with symbolic representation.

constructivist approach A learner-centered approach that emphasizes the individual's active, cognitive construction of knowledge and understanding with guidance from the teacher.

contemporary life-events approach The view that how a life event influences the individual's development depends not only on the event itself but also on mediating factors, the individual's adaptation to the life event, the life-stage context, and the sociohistorical context.

continuity-discontinuity issue Debate that focuses on the extent to which development involves gradual, cumulative change (continuity) or distinct stages (discontinuity).

controversial children Children who are frequently nominated both as someone's best friend and as being disliked.

conventional reasoning The second, or intermediate, level in Kohlberg's theory of moral development. At this level, individuals abide by the standards of others such as parents or the laws of society.

convergent thinking Thinking that produces one correct answer; characteristic of the kind of thinking required on conventional intelligence tests.

coparenting The support that parents provide one another in jointly raising a child.

core knowledge approach States that infants are born with domain-specific innate knowledge systems. Among these domain-specific knowledge systems are those involving space, number sense, object permanence, and language.

corpus callosum A large bundle of axon fibers that connects the brain's left and right hemispheres.

correlation coefficient A number based on a statistical analysis that is used to describe the degree of association between two variables.

correlational research A type of research that strives to describe the strength of the relationship between two or more events or characteristics.

creativity The ability to think in novel and unusual ways and to come up with unique solutions to problems.

crisis A period of identity development during which the individual is exploring alternatives.

critical thinking Thinking reflectively and productively, and evaluating the evidence.

cross-cultural studies Comparisons of one culture with one or more other cultures. These provide information about the degree to which development is similar, or universal, across cultures, and the degree to which it is culture-specific.

cross-sectional approach A research strategy in which individuals of different ages are compared at one time.

crowds A crowd is a larger group than a clique. Adolescents usually are members of a crowd based on reputation and may not spend much time together. Many crowds are defined by the activities in which adolescents engage.

crystallized intelligence An individual's accumulated information and verbal skills, which continues to increase with age.

culture The behavior, patterns, beliefs, and all other products of a group of people that are passed on from generation to generation.

culture-fair tests Intelligence tests that are designed to avoid cultural bias.

D

date or acquaintance rape Coercive sexual activity directed at someone with whom the victim is at least casually acquainted.

dementia A global term for any neurological disorder in which the primary symptom is deterioration of mental functioning.

denial and isolation Kübler-Ross' first stage of dying, in which the dying person denies that she or he is really going to die.

depression Kübler-Ross' fourth stage of dying, in which the dying person perceives the certainty of her or his death. A period of depression or preparatory grief may appear.

descriptive research A type of research that aims to observe and record behavior.

development The pattern of movement or change that begins at conception and continues through the human life span.

developmental cascade model Involves connections across domains over time that influence developmental pathways and outcomes.

developmentally appropriate practice (DAP) Education that focuses on the typical developmental patterns of children (age appropriateness) and the uniqueness of each child (individual appropriateness).

dialect A variety of language that is distinguished by its vocabulary, grammar, or pronunciation.

difficult child A temperament style in which the child tends to react negatively and cry frequently, engages in irregular daily routines, and is slow to accept change.

direct instruction approach A teacher-centered approach characterized by teacher direction and control, high expectations for students' progress, and maximum time spent on academic tasks.

disenfranchised grief Grief involving a deceased person that is a socially ambiguous loss that can't be openly mourned or supported.

disengagement theory The theory that, to cope effectively, older adults should gradually withdraw from society; this theory is not supported by research.

dishabituation The recovery of a habituated response after a change in stimulation.

divergent thinking Thinking that produces many answers to the same question; characteristic of creativity.

divided attention Concentrating on more than one activity at the same time.

DNA A complex molecule that has a double helix shape and contains genetic information.

doula A caregiver who provides continuous physical, emotional, and educational support for the mother before, during, and after childbirth.

Down syndrome A chromosomally transmitted form of intellectual disability caused by the presence of an extra copy of chromosome 21.

dual-process model A model of coping with bereavement that emphasizes oscillation between loss-oriented stressors and restoration-oriented stressors.

dynamic systems theory A theory proposed by Esther Thelen that seeks to explain how infants assemble motor skills for perceiving and acting.

dyscalculia Also known as developmental arithmetic disorder, this term refers to a learning disability that involves difficulty in math computation.

dysgraphia A learning disability that involves difficulty in handwriting.

dyslexia A learning disability that involves a severe impairment in the ability to read and spell.

E

easy child A temperament style in which the child is generally in a positive mood, quickly establishes regular routines, and adapts easily to new experiences.

eclectic theoretical orientation An orientation that does not follow any one theoretical approach but rather selects from each theory whatever is considered best in it.

ecological view The view proposed by the Gibsons that people directly perceive information in the world around them. Perception brings people in contact with the environment in order to interact with it and adapt to it.

ego ideal The component of the superego that rewards the child by conveying a sense of pride and personal value when the child acts according to ideal standards approved by the parents.

egocentrism The inability to distinguish between one's own and someone else's perspective; an important feature of preoperational thought.

elaboration Engagement in more extensive processing of information, benefiting memory.

embryonic period The period of prenatal development that occurs from two to eight weeks after conception. During the embryonic period, the rate of cell differentiation intensifies, support systems for the cells form, and organs appear.

emerging adulthood The developmental time frame occurring from approximately 18 to 25 years of age; this transitional period between adolescence and adulthood is characterized by experimentation and exploration.

emotion Feeling, or affect, that occurs when a person is engaged in an interaction that is important to him or her, especially to his or her well-being.

emotional abuse Acts or omissions by parents or other caregivers that have caused, or could cause, serious behavioral, cognitive, or emotional problems.

emotional intelligence The ability to perceive and express emotions accurately and adaptively, to understand emotion and emotional knowledge, to use feelings to facilitate thought, and to manage emotions in oneself and others.

empathy Reacting to another's feelings with an emotional response that is similar to the other's feelings.

empty nest syndrome View that a decline in marital satisfaction occurs when children leave home; however, research indicates that for most parents there is an upswing in marital satisfaction when children are launched into an adult life.

encoding The process by which information gets into memory.

epigenetic view Perspective emphasizing that development is the result of an ongoing, bidirectional interchange between heredity and environment.

episodic memory Retention of information about the where and when of life's happenings.

equilibration A mechanism that Piaget proposed to explain how children shift from one stage of thought to the next.

Erikson's theory Theory that proposes eight stages of human development. Each stage consists of a unique developmental task that confronts individuals with a crisis that must be resolved.

estradiol A hormone associated in girls with breast, uterine, and skeletal development.

estrogens A class of sex hormones—an important one of which is estradiol—that primarily influences the development of female sex characteristics and helps to regulate the menstrual cycle.

ethnic gloss Use of an ethnic label such as African American or Latino in a superficial way that portrays an ethnic group as being more homogeneous than it really is.

ethnic identity The subjective sense of ethnic group membership that involves self-labeling (Mexican American, for example) and evaluation of one's ethnic group.

ethnicity Categorization of an individual based on cultural heritage, nationality characteristics, race, religion, and language.

ethnocentrism The tendency to consider one's own group superior to other groups.

ethology Theory stressing that behavior is strongly influenced by biology, is tied to evolution, and is characterized by critical or sensitive periods.

euthanasia The act of painlessly ending the lives of persons who are suffering from incurable diseases or severe disabilities; sometimes called "mercy killing."

evocative genotype-environment correlations Correlations that exist when the child's characteristics elicit certain types of environments.

evolutionary psychology A branch of psychology that emphasizes the importance of adaptation, reproduction, and "survival of the fittest" in shaping behavior.

executive attention Cognitive process involving planning actions, allocating attention to goals, detecting and compensating for errors, monitoring progress on tasks, and dealing with novel or difficult circumstances.

executive function An umbrella-like concept that encompasses a number of higher-level cognitive processes linked to the development of the brain's prefrontal cortex. Executive function involves managing one's thoughts to engage in goal-directed behavior and to exercise self-control.

expanding Adding information to the child's incomplete utterance.

experiment Carefully regulated procedure in which one or more factors believed to influence the behavior being studied are manipulated while all other factors are held constant.

expertise Having extensive, highly organized knowledge and understanding of a particular domain.

explicit memory Conscious memory of facts and experiences.

extrinsic motivation Doing something to obtain something else (the activity is a means to an end).

F

fast mapping A process that helps to explain how young children learn the connection between a word and its referent so quickly.

feminization of poverty The fact that far more women than men live in poverty. Women's lower income, divorce, infrequent awarding of alimony, and poorly enforced child support by fathers—which usually leave women with less money than they and their children need to adequately function—are the likely causes.

fertilization A stage in reproduction when an egg and a sperm fuse to create a single cell, called a zygote.

fetal alcohol spectrum disorders (FASD) A cluster of abnormalities that may appear in the offspring of mothers who drink alcohol heavily during pregnancy.

fetal period The prenatal period of development that begins two months after conception and lasts for seven months, on average.

fight or flight Taylor's view that when men experience stress, they are more likely to become aggressive, withdraw from social contact, or drink alcohol.

fine motor skills Motor skills that involve finely tuned movements, such as any activity that requires finger dexterity.

fluid intelligence The ability to reason effectively.

forgiveness An aspect of prosocial behavior that occurs when the injured person releases the injurer from possible behavioral retaliation.

formal operational stage The fourth and final Piagetian stage, which appears between the ages of 11 and 15; individuals move beyond concrete experiences and think in more abstract and logical ways.

fragile X syndrome (FXS) A chromosomal disorder involving an abnormality in the X chromosome, which becomes constricted and often breaks.

free-radical theory A microbiological theory of aging stating that people age because when their cells metabolize energy, they generate waste that includes unstable oxygen molecules, known as free radicals, that damage DNA and other structures.

fuzzy trace theory States that memory is best understood by considering two types of memory representations: (1) verbatim memory trace and (2) gist.

fuzzy-trace theory dual-process model States that decision making is influenced by two systems—"verbatim" analytical (literal and precise) and gist-based intuition (simple bottom-line meaning)—which operate in parallel; in this model, gist-based intuition benefits adolescent decision making more than analytical thinking does.

G

games Activities that are engaged in for pleasure and include rules.

gender Characteristics related to femininity and masculinity based on social and cultural norms.

gender identity A person's inner sense of being a girl/woman, boy/man, another gender, or no gender, which develops early in childhood and remains stable across time for most people but which may change throughout the life course for others.

gender roles Sets of expectations that prescribe how people should think, act, and feel based on social and cultural norms about gender.

gender schema theory The theory that gender-typing emerges as children gradually develop gender schemas of what is gender-appropriate and gender-inappropriate in their culture.

gender stereotypes General impressions and beliefs about girls/women and boys/men.

gender-intensification hypothesis The view that psychological and behavioral differences between boys and girls become greater during early adolescence because of increased socialization pressures to conform to traditional gender roles.

gender-typing Acquisition of a traditional masculine or feminine role.

gene × environment (G × E) interaction The interaction of a specific measured variation in the DNA and a specific measured aspect of the environment.

generativity versus stagnation The seventh stage in Erikson's life-span theory; it encompasses adults' desire to leave a legacy of themselves to the next generation.

genes Units of hereditary information composed of DNA. Genes help cells to reproduce themselves and assemble proteins that direct body processes.

genotype All of a person's actual genetic material.

germinal period The period of prenatal development that takes place during the first two weeks after conception; it includes the creation of the zygote, continued cell division, and the attachment of the zygote to the wall of the uterus.

giftedness Having above-average intelligence (an IQ of 130 or higher) and/or superior talent for something.

glaucoma Damage to the optic nerve because of pressure created by a buildup of fluid in the eye.

gonadotropins Hormones that stimulate the testes or ovaries.

gonads The sex glands, which are the testes in males and the ovaries in females.

goodness of fit The match between a child's temperament and the environmental demands the child must cope with.

grasping reflex A reflex that occurs when something touches an infant's palms. The infant responds by grasping tightly.

gratitude A feeling of thankfulness and appreciation, especially in response to someone's doing something kind or helpful.

grief The emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love.

grit Involves passion and persistence in achieving long-term goals.

gross motor skills Motor skills that involve large-muscle activities, such as walking.

H

habituation Decreased responsiveness to a stimulus after repeated presentations of the stimulus.

helpless orientation An orientation in which one seems trapped by the experience of difficulty and attributes one's difficulty to a lack of ability.

heteronomous morality The first stage of moral development in Piaget's theory, occurring at 4 to 7 years of age. Justice and rules are conceived of as unchangeable properties of the world, removed from the control of people.

hidden curriculum The pervasive moral atmosphere that characterizes every school.

hormonal stress theory The theory that aging in the body's hormonal system can lower resistance to stress and increase the likelihood of disease.

hormones Powerful chemical substances secreted by the endocrine glands and carried through the body by the bloodstream.

hospice A program committed to making the end of life as free from pain, anxiety, and depression as possible. The goals of hospice contrast with those of a hospital, which are to cure disease and prolong life.

hypothalamus A structure in the brain that is involved with eating and sexual behavior.

hypotheses Specific assumptions and predictions that can be tested to determine their accuracy.

hypothetical-deductive reasoning Piaget's formal operational concept that adolescents have the cognitive ability to develop hypotheses about ways to solve problems and can systematically deduce which is the best path to follow in solving the problem.

I

identity achievement Marcia's term for the status of individuals who have undergone a crisis and have made a commitment.

identity diffusion Marcia's term for the status of individuals who have not yet experienced a crisis (explored meaningful alternatives) or made any commitments.

identity foreclosure Marcia's term for the status of individuals who have made a commitment but have not experienced a crisis.

identity moratorium Marcia's term for the status of individuals who are in the midst of a crisis but whose commitments are either absent or vaguely defined.

identity versus identity confusion Erikson's fifth stage of development, which occurs during the adolescent years; adolescents are faced with finding out who they are, what they are all about, and where they are going in life.

imaginary audience That aspect of adolescent egocentrism that involves feeling that one is the center of attention and sensing that one is on stage.

immanent justice Belief that if a rule is broken, punishment will be meted out immediately.

implicit memory Memory without conscious recollection—memory of skills and routine procedures that are performed automatically.

inclusion Education of a child with special educational needs full-time in the regular classroom.

individualism Giving priority to personal goals rather than to group goals; emphasizing values that serve the self, such as feeling good, obtaining personal distinction through achievement, and preserving independence.

individuality Characteristic consisting of two dimensions: self-assertion, the ability to have and communicate a point of view; and separateness, the use of communication patterns to express how one is different from others.

individualized education plan (IEP) A written statement that spells out a program tailored to a child with a disability. The plan should be (1) related to the child's learning capacity, (2) specially constructed to meet the child's individual needs and not merely a copy of what is offered to other children, and (3) designed to provide educational benefits.

indulgent parenting A style in which parents are very involved with their children but place few demands or controls on them.

infinite generativity The ability to produce and comprehend an endless number of meaningful sentences using a finite set of words and rules.

information-processing theory Theory emphasizing that individuals manipulate information, monitor it, and strategize about it. Central to this theory are the processes of memory and thinking.

insecure avoidant children Children who show insecurity by avoiding the mother.

insecure disorganized children Children who show insecurity by being disorganized and disoriented.

insecure resistant children Children who might cling to the caregiver, then resist by fighting against the closeness, perhaps by kicking or pushing away.

intellectual disability A condition of limited mental ability in which an individual has a low IQ, usually below 70 on a traditional test of intelligence, and has difficulty adapting to the demands of everyday life.

intelligence quotient (IQ) An individual's mental age divided by chronological age, multiplied by 100; devised in 1912 by William Stern.

intelligence The ability to solve problems and to adapt to and learn from experiences.

intermodal perception The ability to integrate information about two or more sensory modalities, such as vision and hearing.

intimacy in friendship Self-disclosure and the sharing of private thoughts.

intrinsic motivation Doing something for its own sake; involves factors such as self-determination and opportunities to make choices.

intuitive thought substage The second substage of preoperational thought, occurring between approximately 4 and 7 years of age. Children begin to use primitive reasoning and want to know the answers to all sorts of questions.

J

joint attention Focus by individuals on the same object or event; requires an ability to track another's behavior, one individual to direct another's attention, and reciprocal interaction.

justice perspective A moral perspective that focuses on the rights of the individual; individuals independently make moral decisions.

juvenile delinquency Actions taken by an adolescent in breaking the law or engaging in illegal behavior.

K

kangaroo care A way of holding a preterm infant so that there is skin-to-skin contact.

Klinefelter syndrome A chromosomal disorder in which males have an extra X chromosome, making them XXY instead of XY.

L

labeling Naming objects that children seem interested in.

laboratory A controlled setting from which many of the complex factors of the "real world" have been removed.

language A form of communication, whether spoken, written, or signed, that is based on a system of symbols.

language acquisition device (LAD) Chomsky's term that describes a biological endowment that enables the child to detect certain features and rules of language, including phonology, syntax, and semantics.

lateralization Specialization of function in one hemisphere or the other of the cerebral cortex.

learning disabilities Disabilities in which children experience difficulty in learning that involves understanding or using spoken or written language; the difficulty can appear in listening, thinking, reading, writing, and spelling. A learning disability also may involve difficulty in doing mathematics. To be classified as a learning disability, the learning problem is not primarily the result of visual, hearing, or motor disabilities; intellectual disability; emotional disorders; or environmental, cultural, or economic disadvantage.

least restrictive environment (LRE) A setting that is as similar as possible to the one in which children without a disability are educated.

leisure The pleasant times when individuals are free to pursue activities and interests of their own choosing.

life span The upper boundary of life, which is the maximum number of years an individual can live. The maximum life span of humans is about 120 years of age.

life-span perspective View of development as being lifelong, multidimensional, multidirectional, plastic, multidisciplinary, and contextual; involving growth, maintenance, and regulation of loss; and constructed through biological, sociocultural, and individual factors working together.

limbic system The region of the brain where emotions and rewards are experienced.

long-term memory A relatively permanent and unlimited type of memory.

longitudinal approach A research strategy in which the same individuals are studied over a period of time, usually several years or more.

low birth weight infants Infants who weigh less than 5½ pounds at birth.

M

macular degeneration A vision problem in the elderly that involves deterioration of the macula of the retina.

mastery orientation A perspective in which one is task-oriented—concerned with learning strategies and the process of achievement rather than the outcome.

meaning-making coping Drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of high levels of stress such as when a loved one dies.

meiosis A specialized form of cell division that occurs to form eggs and sperm (or gametes).

memory Retention of information over time.

menarche A girl's first menstrual period.

menopause The complete cessation of a woman's menstrual cycles, which usually occurs during the late forties or early fifties.

mental age (MA) An individual's level of mental development relative to that of others.

metacognition Cognition about cognition, or "knowing about knowing."

metalinguistic awareness Knowledge about language.

metamemory Knowledge about memory.

metaphor An implied comparison between two unlike things.

mindset The cognitive view individuals develop for themselves that perceives their potential either as fixed or as capable of growth.

mitochondrial theory The theory that aging is caused by the decay of the mitochondria, which are tiny cellular bodies that supply energy for cell function, growth, and repair.

mitosis Cellular reproduction in which the cell's nucleus duplicates itself; two new cells are formed, each containing the same DNA as the original cell, arranged in the same 23 pairs of chromosomes.

Montessori approach An educational philosophy in which children are given considerable freedom and spontaneity in choosing activities and are allowed to move from one activity to another as they desire.

moral development Changes in thoughts, feelings, and behaviors regarding standards of right and wrong.

moral exemplars People who have a moral personality, identity, character, and set of virtues that reflect moral excellence and commitment.

moral identity The aspect of personality that is present when individuals have moral notions and commitments that are central to their lives.

Moro reflex A startle response that occurs in reaction to a sudden, intense noise or movement. When startled, the newborn arches its back, throws its head back, and flings out its arms and legs. Then the newborn rapidly closes its arms and legs to the center of the body.

morphology Units of meaning involved in word formation.

mTOR pathway A cellular pathway that involves the regulation of growth and metabolism and has been proposed as a key aspect of longevity.

myelination The process of encasing axons with a myelin sheath, thereby improving the speed and efficiency of information processing.

N

narcissism A self-centered and self-concerned approach toward others.

natural childbirth A childbirth method that attempts to reduce the mother's pain by decreasing her fear through education about childbirth stages and relaxation techniques during delivery.

naturalistic observation Observing behavior in real-world settings.

nature-nurture issue Debate about whether development is primarily influenced by nature or nurture. Nature refers to an organism's biological inheritance, nurture to its environmental experiences. The "nature proponents" claim biological inheritance is the more important influence on development; the "nurture proponents" claim that environmental experiences are more important.

neglected children Children who are infrequently nominated as a best friend but are not disliked by their peers.

neglectful parenting A style in which the parent is very uninvolved in the child's life.

neo-Piagetians Developmentalists who have elaborated on Piaget's theory, emphasizing attention to children's strategies; information-processing speed; the task involved; and division of the problem into more precise, smaller steps.

neuroconstructivist view Developmental perspective in which biological processes and environmental conditions influence the brain's development; the brain has plasticity and is context dependent; and cognitive development is closely linked with brain development.

neurogenesis The generation of new neurons.

neurons Nerve cells that handle information processing at the cellular level.

nonnormative life events Unusual occurrences that have a major impact on an individual's life.

normal distribution A symmetrical, bell-shaped curve with a majority of the cases falling in the middle of the possible range of scores and few scores appearing toward the extremes of the range.

normative age-graded influences Influences that are similar for individuals in a particular age group.

normative history-graded influences Influences that are common to people of a particular generation because of historical circumstances.

O

object permanence The Piagetian term for one of an infant's most important accomplishments: understanding that objects continue to exist even when they cannot directly be seen, heard, or touched.

operations Reversible mental actions that allow children to do mentally what before they had done only physically.

optimism A style of thinking that involves having a positive outlook on the future and minimizing problems.

organization Piagetian concept of grouping isolated behaviors and thoughts into a higher-order, more smoothly functioning cognitive system.

organogenesis Process of organ formation that takes place during the first two months of prenatal development.

osteoporosis A disorder that involves an extensive loss of bone tissue and is the main reason many older adults walk with a marked stoop. Women are especially vulnerable to osteoporosis.

P

pain cry A sudden, initial loud cry followed by breath holding, without preliminary moaning.

palliative care Emphasized in hospice care; involves reducing pain and suffering and helping individuals die with dignity.

Parkinson disease A chronic, progressive disease characterized by muscle tremors, slowing of movement, and partial facial paralysis.

passive euthanasia The withholding of available treatments, such as life-sustaining devices, and allowing the person to die.

passive genotype-environment correlations Correlations that exist when the biological parents, who are genetically related to the child, provide a rearing environment for the child.

peers Individuals who share the same age or maturity level.

perception The interpretation of sensation.

performance orientation An orientation in which one focuses on winning, rather than on achievement outcome; happiness is thought to result from winning.

perimenopause The transitional period from normal menstrual periods to no menstrual periods at all, which often takes up to 10 years.

personal fable The part of adolescent egocentrism that involves an adolescent's sense of personal uniqueness and invincibility.

perspective taking The ability to assume another person's perspective and understand his or her thoughts and feelings.

phenotype Observable and measurable characteristics of an individual, such as height, hair color, and intelligence.

phenylketonuria (PKU) A genetic disorder in which an individual cannot properly metabolize phenylalanine, an amino acid; PKU is now easily detected—but, if left untreated, results in intellectual disability and hyperactivity.

phonics approach A teaching approach built on the idea that reading instruction should teach basic rules for translating written symbols into sounds.

phonology The sound system of a language—includes the sounds used and how they may be combined.

physical abuse Infliction of physical injury by punching, beating, kicking, biting, burning, shaking, or otherwise harming a child.

Piaget's theory Theory stating that children actively construct their understanding of the world and go through four stages of cognitive development.

pituitary gland An important endocrine gland that controls growth and regulates the activity of other glands.

play A pleasurable activity that is engaged in for its own sake.

play therapy Therapy that lets children work off frustrations while therapists analyze their conflicts and coping methods.

popular children Children who are frequently nominated as a best friend and are rarely disliked by their peers.

possible selves What adolescents hope to become as well as what they dread they might become.

postconventional reasoning The highest level in Kohlberg's theory of moral development. At this level, the individual recognizes alternative moral courses, explores the options, and then decides on a personal moral code.

postformal thought Thinking that is reflective, relativistic, and contextual; provisional; realistic; and influenced by emotions.

postpartum depression A major depressive episode that typically occurs about four weeks after delivery; women with this condition have such strong feelings of sadness, anxiety, or despair that they have trouble coping with daily tasks during the postpartum period.

postpartum period The period after childbirth when the mother adjusts, both physically and psychologically, to the process of childbirth. This period lasts for about six weeks or until her body has completed its adjustment and returned to a near prepregnant state.

practice play Play that involves repetition of behavior when new skills are being learned or when mastery and coordination of skills are required for games or sports.

pragmatics The appropriate use of language in different contexts.

preconventional reasoning The lowest level in Kohlberg's theory of moral development. The individual's moral reasoning is controlled primarily by external rewards and punishments.

prefrontal cortex The highest level of the frontal lobes that is involved in reasoning, decision making, and self-control.

preoperational stage The second Piagetian developmental stage, which lasts from about 2 to 7 years of age; children begin to represent the world with words, images, and drawings.

prepared childbirth Developed by French obstetrician Ferdinand Lamaze, a childbirth strategy similar to natural childbirth but one that teaches a special breathing technique to control pushing in the final stages of labor and provides details about anatomy and physiology.

pretense/symbolic play Play that occurs when a child transforms aspects of the physical environment into symbols.

preterm infants Infants born three weeks or more before the pregnancy has reached its full term.

primary emotions Emotions that are present in humans and other animals, emerge early in life, and are culturally universal; examples are joy, anger, sadness, fear, and disgust.

Project Head Start Compensatory prekindergarten education designed to provide children from low-income families the opportunity to acquire skills and experiences important for school success.

prospective memory Remembering to do something in the future.

proximodistal pattern The sequence in which growth starts at the center of the body and moves toward the extremities.

psychoanalytic theories Theories that describe development as primarily unconscious and heavily colored by emotion. Behavior is merely a surface characteristic, and the symbolic workings of the mind must be analyzed to understand behavior. Early experiences with parents are emphasized.

psychoanalytic theory of gender Theory that stems from Freud's view that preschool children develop a sexual attraction to the opposite-sex parent, then at 5 or 6 years of age renounce the attraction because of anxious feelings, subsequently identifying with the same-sex parent and unconsciously adopting the same-sex parent's characteristics.

psychosocial moratorium Erikson's term for the gap between childhood security and adult autonomy that adolescents experience as part of their identity exploration.

puberty A brain-neuroendocrine process occurring primarily in early adolescence that provides stimulation for the rapid physical changes that occur in this period of development.

R

racial identity The collective identity of any group of people socialized to think of themselves as a racial group.

racism Discrimination, prejudice, or antagonism against a person or people based on their racial or ethnic group.

rape Forcible sexual intercourse, oral sex, or anal sex with a person who does not give consent. Legal definitions of rape differ from state to state.

rapport talk The language of conversation; a way to establish connections and negotiate relationships; preferred by women.

recasting Involves an adult's rephrasing of a child's statement that might lack the appropriate morphology or contain some other error. The adult restates the child's immature utterance in the form of a fully grammatical sentence.

reciprocal socialization Socialization that is bidirectional in that children socialize parents just as parents socialize children.

reflexive smile A smile that does not occur in response to external stimuli. It happens during the month after birth, usually during sleep.

rejected children Children who are infrequently nominated as a best friend and are actively disliked by their peers.

religion An organized set of beliefs, practices, rituals, and symbols that increases an individual's connection to a sacred or transcendent other (God, higher power, or higher truth).

religiousness The degree of affiliation with an organized religion, participation in prescribed rituals and practices, connection with its beliefs, and involvement in a community of believers.

report talk Language designed to convey information; a communication style preferred by men.

romantic love Also called passionate love, or eros, this type of love has strong components of sexuality and infatuation, and it often predominates in the early part of a love relationship.

romantic script A perspective in which sex is synonymous with love; belief that if we develop a relationship with someone and fall in love, it is acceptable to have sex with the person whether we are married or not.

rooting reflex A newborn's built-in reaction that occurs when the infant's cheek is stroked or the side of the mouth is touched. In response, the infant turns its head toward the side that was touched, in an apparent effort to find something to suck.

S

satire The use of irony, derision, or wit to expose folly or wickedness.

scaffolding In cognitive development, a term Vygotsky used to describe the changing level of support over the course of a teaching session, with the more-skilled person adjusting guidance to fit the child's current performance level.

schema theory Theory stating that people mold memories to fit information that already exists in their minds.

schemas Mental frameworks that organize concepts and information.

schemes In Piaget's theory, actions or mental representations that organize knowledge.

secure attachment style An attachment style that describes adults who have positive views of relationships, find it easy to get close to others, and are not overly concerned or stressed out about their romantic relationships.

securely attached children Children who use the caregiver as a secure base from which to explore the environment.

selective attention Focusing on a specific aspect of experience that is relevant while ignoring others that are irrelevant.

selective optimization with compensation theory The theory that successful aging involves three strategies: selection, optimization, and compensation.

self-concept Domain-specific evaluations of the self.

self-conscious emotions Emotions that require consciousness and a sense of "me"; they include empathy, jealousy, embarrassment, pride, shame, and guilt, most of which first appear at some point after 18 months of age when a sense of self becomes consolidated in toddlers.

self-efficacy The belief that one can master a situation and produce favorable outcomes.

self-esteem The global evaluative dimension of the self. Self-esteem is also referred to as self-worth or self-image.

self-regulation The ability to control one's behavior without having to rely on others for help.

self-understanding The individual's cognitive representation of the self, the substance of self-conceptions.

semantic memory A person's knowledge about the world, including fields of expertise, general academic knowledge, and "everyday knowledge" about meanings of words, names of famous individuals, important places, and common things.

semantics The meanings of words and sentences.

sensation Reaction that occurs when information interacts with sensory receptors—the eyes, ears, tongue, nostrils, and skin.

sensorimotor play Behavior in which infants derive pleasure from exercising their sensorimotor schemes.

sensorimotor stage The first of Piaget's stages, which lasts from birth to about 2 years of age, during which infants construct an understanding of the world by coordinating sensory experiences (such as seeing and hearing) with physical, motoric actions.

separation protest Reaction that occurs when infants experience a fear of being separated from a caregiver, which results in crying when the caregiver leaves.

seriation The concrete operation that involves ordering stimuli along a quantitative dimension (such as length).

service learning A form of education that promotes social responsibility and service to the community.

sexual abuse Fondling a child's genitals, intercourse, incest, rape, sodomy, exhibitionism, and commercial exploitation through prostitution or the production of pornographic materials.

sexual harassment Sexual persecution that can take many forms—from sexist remarks and physical contact (patting, brushing against someone's body) to blatant propositions and sexual assaults.

sexual scripts Stereotyped patterns of expectancies for how people should behave sexually.

sexually transmitted infections (STIs) Diseases that are contracted primarily through sexual contact, including oral-genital contact, anal-genital contact, and vaginal intercourse.

shape constancy Recognition that an object remains the same even though its orientation to the viewer changes.

short-term memory Retention of information for up to 15 to 30 seconds, without rehearsal of the information. Using rehearsal, individuals can keep the information in short-term memory longer.

sickle-cell anemia A genetic disorder that affects the red blood cells and occurs most often in African Americans.

sirtuins A family of proteins that have been proposed as having important influences on longevity, mitochondrial functioning in energy, calorie restriction benefits, stress resistance, and cardiovascular functioning.

size constancy Recognition that an object remains the same even though the retinal image of the object changes as the viewer moves toward or away from the object.

slow-to-warm-up child A temperament style in which the child has a low activity level, is somewhat negative, and displays a low intensity of mood.

small for date infants Infants whose birth weights are below normal when the length of pregnancy is considered; also called small for gestational age infants. Small for date infants may be preterm or full-term.

social cognitive theory Theoretical view that behavior, environment, and cognition are the key factors in development.

social cognitive theory of gender The idea that children's gender development occurs through observation and imitation of gender behavior, as well as through the rewards and punishments children experience for behaviors believed to be appropriate or inappropriate for their gender.

social cognitive theory of morality The theory that distinguishes between moral competence—the ability to produce moral behaviors—and moral performance—performing those behaviors in specific situations.

social constructivist approach An emphasis on the social contexts of learning and construction of knowledge through social interaction. Vygotsky's theory reflects this approach.

social conventional reasoning Focuses on conventional rules established by social consensus and convention, as opposed to moral reasoning, which stresses ethical issues.

social domain theory Theory that identifies different domains of social knowledge and reasoning, including moral, social conventional, and personal domains. These domains arise from children's and adolescents' attempts to understand and deal with different forms of social experience.

social play Play that involves interaction with peers.

social policy A government's course of action designed to promote the welfare of its citizens.

social referencing "Reading" emotional cues in others to help determine how to act in a specific situation.

social role theory Eagly's theory that psychological gender differences are caused by the contrasting social roles of women and men.

social smile A smile in response to an external stimulus, which, early in development, typically is a face.

socioeconomic status (SES) Classification of a person's position in society based on occupational, educational, and economic characteristics.

socioemotional processes Processes that involve changes in an individual's relationships with other people, emotions, and personality.

socioemotional selectivity theory The theory that older adults become more selective about their activities and social relationships in order to maintain emotional well-being.

source memory The ability to remember where something was learned.

spirituality Experiencing something beyond oneself in a transcendent manner and living in a way that benefits others and society.

stability-change issue Debate as to whether and to what degree we become older renditions of our earlier selves (stability) or whether we develop into someone different from who we were at an earlier point in development (change).

standardized test A test with uniform procedures for administration and scoring. Many standardized tests allow a person's performance to be compared with the performance of other individuals.

stereotype threat Anxiety regarding whether one's behavior might confirm a negative stereotype about one's group.

Strange Situation Ainsworth's observational measure of infant attachment to a caregiver that requires the infant to move through a series of introductions, separations, and reunions with the caregiver and an adult stranger in a prescribed order.

stranger anxiety An infant's fear of and wariness toward strangers; it tends to appear in the second half of the first year of life.

strategy construction Creation of new procedures for processing information.

sucking reflex A newborn's reaction of sucking an object placed in its mouth. The sucking reflex enables the infant to get nourishment before it has begun to associate a nipple with food.

sudden infant death syndrome (SIDS) Condition in which an infant stops breathing, usually during the night, and suddenly dies without an apparent cause.

sustained attention The ability to maintain attention to a selected stimulus for a prolonged period of time.

symbolic function substage The first substage of preoperational thought, occurring roughly between the ages of 2 and 4. In this substage, the young child gains the ability to represent mentally an object that is not present.

sympathy An emotional response to another person in which the observer feels sad or concerned about the person's well-being.

syntax The ways words are combined to form acceptable phrases and sentences.

T

telegraphic speech The use of short, precise words without grammatical markers such as articles, auxiliary verbs, and other connectives.

temperament An individual's behavioral style and characteristic way of responding.

tend and befriend Taylor's view that when women experience stress, they are more likely to seek social alliances with others, especially female friends.

teratogen Any agent that can potentially cause a birth defect or negatively alter cognitive and behavioral outcomes.

testosterone A hormone associated in boys with the development of the genitals, increased height, and voice changes.

theory An interrelated, coherent set of ideas that helps to explain phenomena and make predictions.

theory of mind Thoughts about how one's own mental processes work and the mental processes of others.

thinking Manipulating and transforming information in memory, in order to reason, reflect, think critically, evaluate ideas and solve problems, and make decisions.

top-dog phenomenon The circumstance of moving from the top position in elementary school to the youngest, smallest, and least powerful position in middle or junior high school.

traditional religious script View that sex is acceptable only within marriage; extramarital sex is taboo, especially for women; and sex means reproduction and sometimes affection.

trait theories Theories emphasizing that personality consists of broad dispositions, called traits, which tend to produce characteristic responses.

transgender A broad term that refers to individuals who adopt a gender identity that differs from the one assigned to them at birth.

transitivity The ability to logically combine relations to understand certain conclusions. Piaget argued that an understanding of transitivity is characteristic of concrete operational thought.

triangular theory of love Sternberg's theory that love includes three components or dimensions—passion, intimacy, and commitment.

triarchic theory of intelligence Sternberg's theory that intelligence consists of analytical intelligence, creative intelligence, and practical intelligence.

Turner syndrome A chromosomal disorder in females in which either an X chromosome is missing, making the person XO instead of XX, or part of one X chromosome is deleted.

twin study A study in which the behavioral similarity of identical twins is compared with the behavioral similarity of fraternal twins.

V

values Beliefs and attitudes about the way things should be.

visual preference method A method developed by Fantz to determine whether infants can distinguish one stimulus from another by measuring the length of time they attend to different stimuli.

Vygotsky's theory Sociocultural cognitive theory that emphasizes how culture and social interaction guide cognitive development.

W

Wernicke's area An area of the brain's left hemisphere that is involved in language comprehension.

whole-language approach A teaching approach built on the idea that reading instruction should parallel children's natural language learning and that reading materials should be whole and meaningful.

wisdom Expert knowledge about the practical aspects of life that permits excellent judgment about important matters.

working memory A mental "workbench" where individuals manipulate and assemble information when making decisions, solving problems, and comprehending written and spoken language.

X

XYY syndrome A chromosomal disorder in which males have an extra Y chromosome.

Z

zone of proximal development (ZPD) Vygotsky's term for tasks that are too difficult for children to master alone but can be mastered with guidance and assistance from adults or more-skilled children.

zygote A single cell formed through fertilization.
